Chasing the Cosmic Dawn with LEDA

Tuesday, 5 October 2021 15:30 (20 minutes)

Total-power radiometry with individual meter-wave antennas is a potentially effective way to study the Cosmic Dawn ($z \sim 20$) through measurement of the sky brightness arising from the 21-cm transition of neutral hydrogen, provided this can be disentangled from much stronger Galactic and extra-galactic foregrounds. In the process, measured spectra of integrated sky brightness temperature can be used to quantify the foreground emission properties.

In this talk, I present results from a subset of data from the Large-aperture Experiment to Detect the Dark Age (LEDA) in the 50 – 87~MHz range. I will present the constraints on the foreground spectral index β in the northern sky visible from mid-latitudes, focusing on two zenith-directed LEDA radiometers, and discuss how estimates of β vary with local sidereal time (LST). Combining all data gathered during the extended campaign between mid-2018 to mid-2019, I will discuss the progress made in the quest for a cosmological signal.
