

Mind the gaps: a massive empirical approach to high-mass stellar evolution

with the aid of IACOB, WEAVE, Gaia and TESS

Sergio Simón-Díaz

Instituto de Astrofísica de Canarias, Tenerife, Spain

+ Gonzalo Holgado, Abel de Burgos, Siemen Burssens
and the IACOB team

The IACOB project: an ambitious long term observational project

Main Scientific Goal

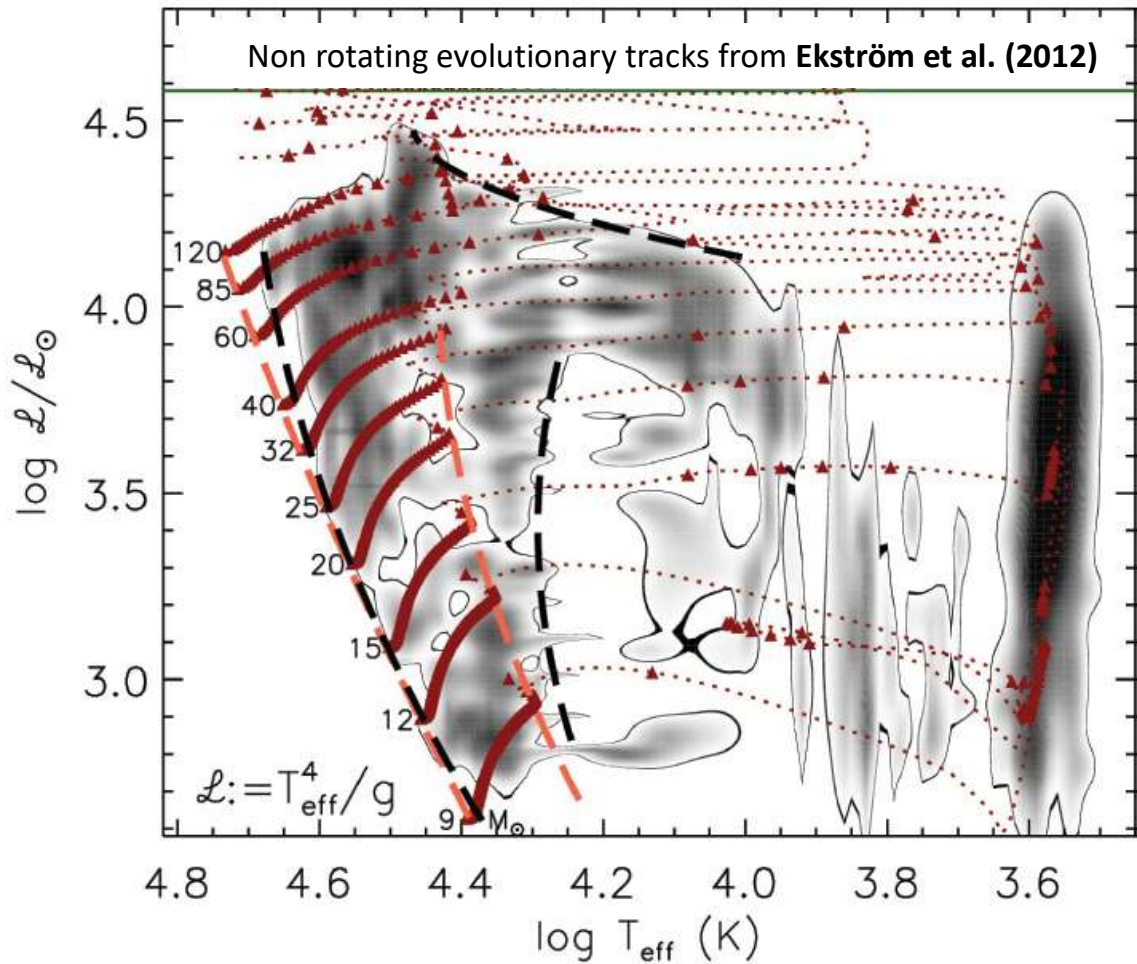

Provide an **(unprecedented) holistic empirical overview** of the main physical properties of Galactic massive O- and B-type stars which can be used as reliable and long-lasting **anchor point** for our theories of stellar atmospheres, winds, interiors and evolution of massive stars.

This story began in November 2008 at the Nordic 2.56m optical telescope (NOT, ORM, La Palma, Spain) ...

... 5 years before  **gaia** was launched

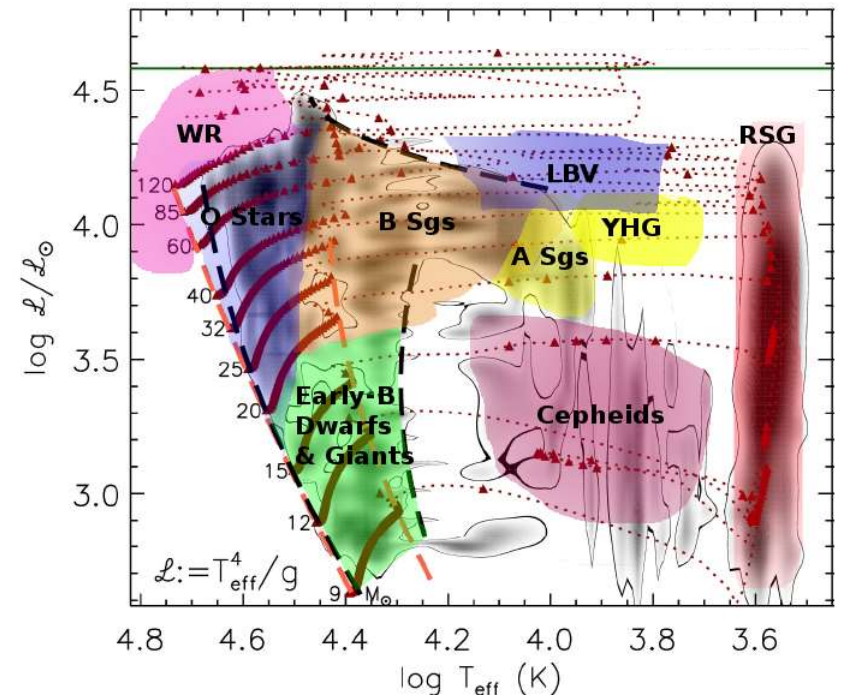

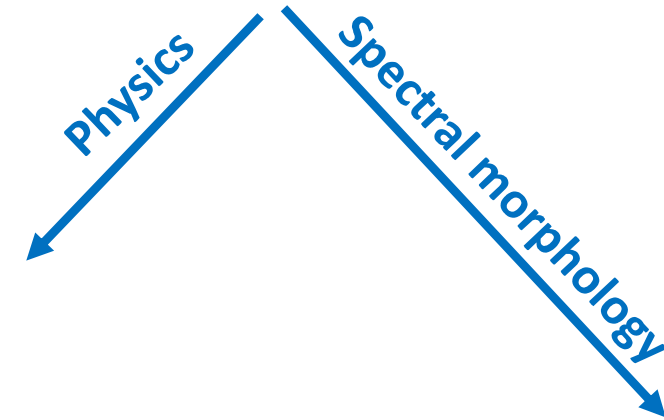

Welcome back to the realm of high-mass (aka massive) stars

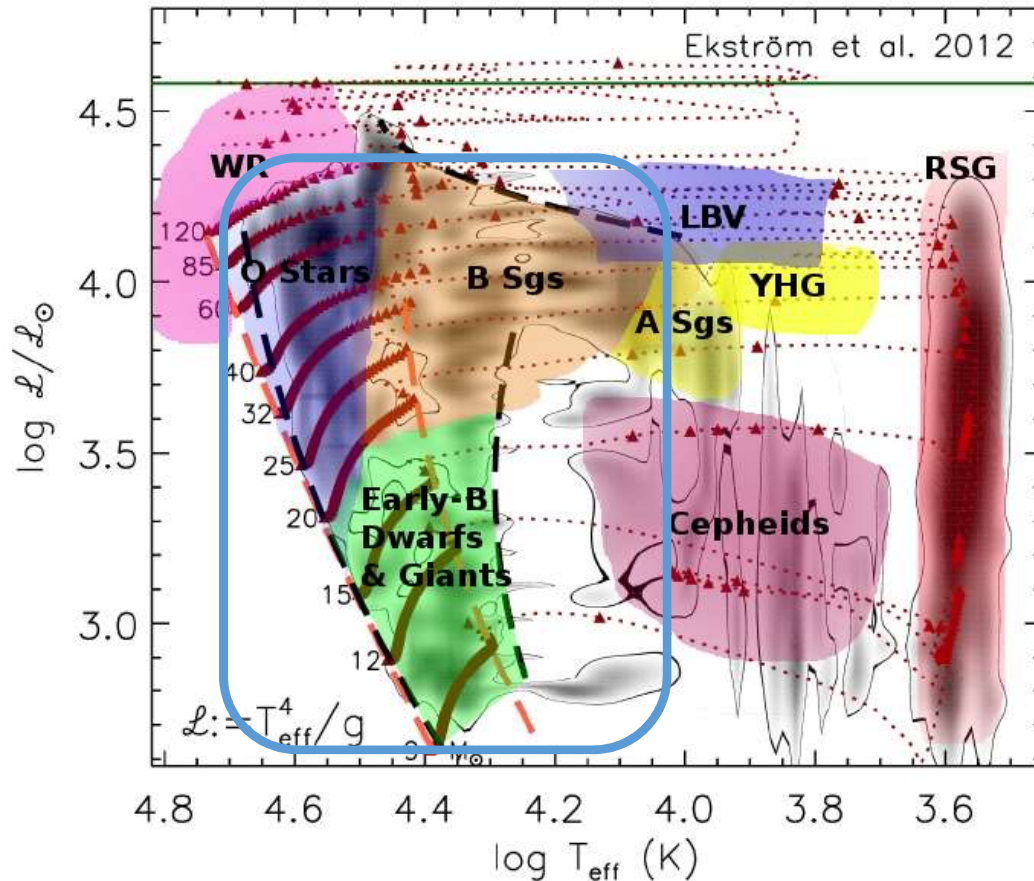

Massive star: a star that is massive enough to form a collapsing core at the end of its life and, thus, avoid the white dwarf fate (**Langer 2012**)

Density map (in the sHRD) of ~ 600 Galactic massive stars with parameters determined spectroscopically (**Castro et al. 2014**)

G. Holgado (2019, PhD thesis)

The realm of blue massive (OB-type) stars

Massive stars spent most of their time* as:

OB stars

Main physical properties

Massive ($M > 8 M_{\odot}$)

Hot ($T_{\text{eff}} > 10 \text{ kK}$, $T_{\text{eff, ZAMS}} > 20 \text{ kK}$)

Large ($R = 5 - 80 R_{\odot}$)

Luminous ($L = 10^3 - 10^6 L_{\odot}$)

Windy ($\dot{M}_{\text{dot}} = 10^{-9} - 10^{-5} M_{\odot}/\text{yr}$)

Strong ionizing radiation ($T_{\text{eff}} > 30 \text{ kK}$, mainly O stars)

Young (a few Myr)

* Roughly speaking massive stars spend 90% of their time in the Main Sequence

In the Milky Way ...

They are mainly found in (young) star forming regions across the Galactic disk. But not all of them ...

The IACOB project: an ambitious long term observational project

Main Scientific Goal

Provide an **(unprecedented) holistic empirical overview** of the main physical properties of Galactic massive O- and B-type stars which can be used as reliable and long-lasting **anchor point** for our theories of stellar atmospheres, winds, interiors and evolution of massive stars.

Immediate objective

Thorough empirical characterization of a **statistically meaningful sample⁽¹⁾** of Galactic massive stars covering the full OB star domain.

⁽¹⁾ Ideally, **several thousand**

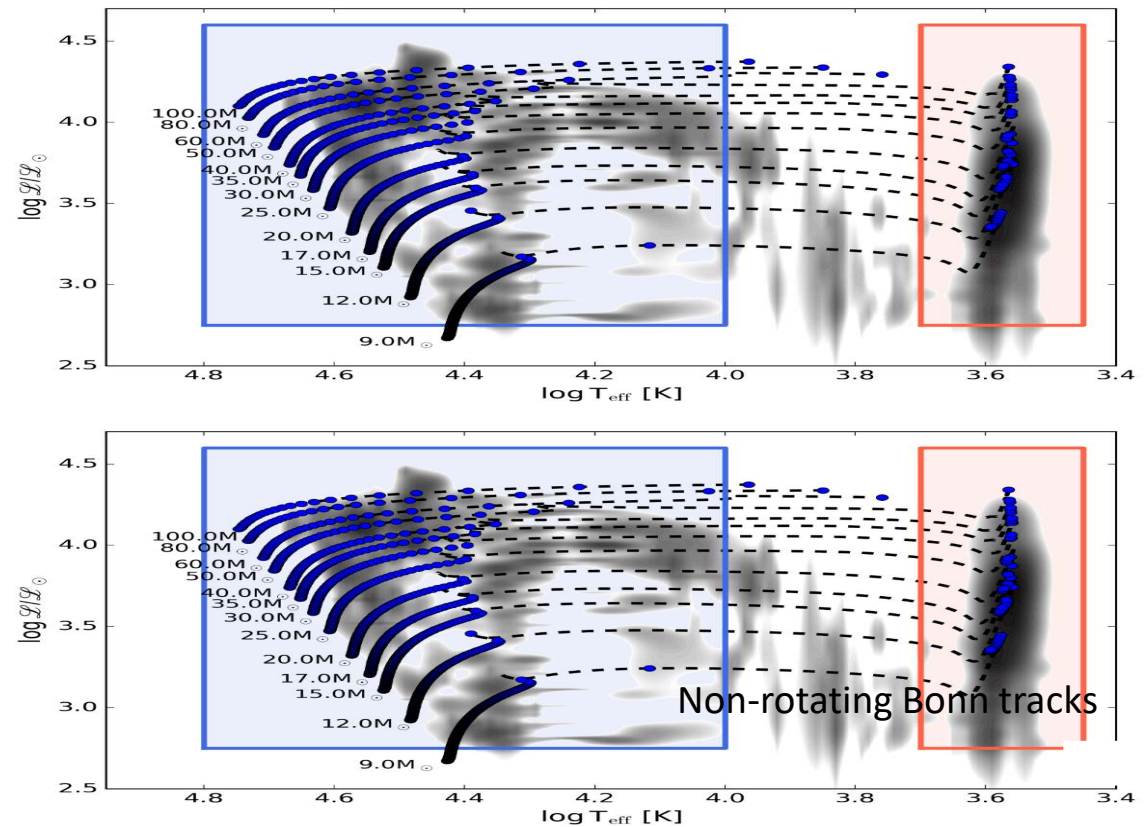

More specific objectives

- Compilation of the required **observations**
- Determination of the whole set of **stellar and wind parameters**
- Determination of a set of **surface abundances**
- Identification and empirical study of **binary/multiple systems**
- Identification and characterization of **stellar variability**

But ... why is so important to consider so many stars?

Establishing the link between the **empirical properties** of an OB star and its **evolutionary status** would be simple if massive star evolution would only depend on mass ...

Immediate objective

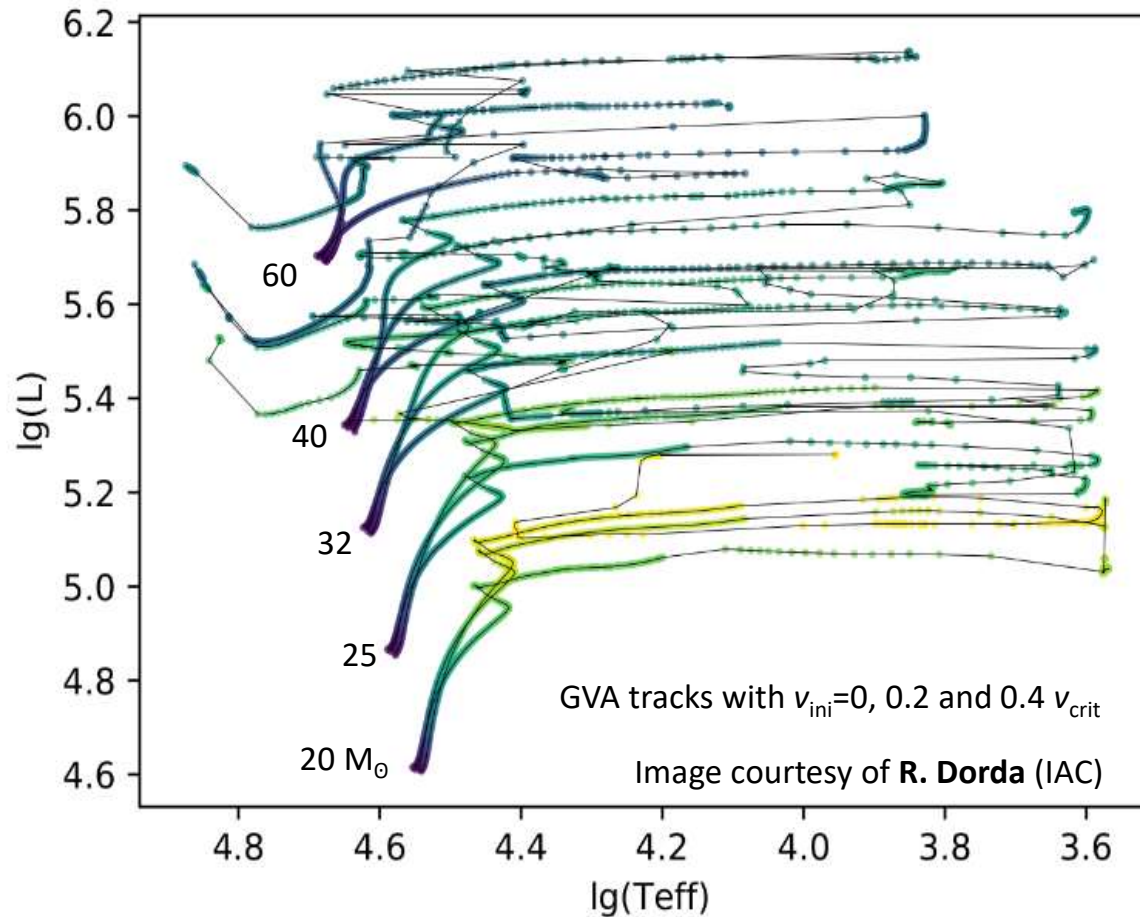

Thorough empirical characterization of a **statistically meaningful sample**⁽¹⁾ of Galactic massive stars covering the full OB star domain.

(1) Ideally, **several thousand**

Image adapted from Castro et al. (2014). Courtesy of **N. Castro (IAP)**

But ... why is so important to consider so many stars?

... but massive star evolution does not only depend on mass, but also on **rotation** and **stellar winds**⁽¹⁾

Note 1: The measured ***vsini*** of massive stars range from a few km/s to 450 km/s (e.g. *Conti & Ebbet 1977, Holgado 2022*)

Note 2: A massive star can enter the **blue supergiant region** either by evolving directly from the main sequence, or from a previous red supergiant stage (e.g., *Ekström et al. 2012*)

⁽¹⁾ Plus core overshooting, internal transport of angular momentum and chemical species, metallicity, ...

Image courtesy of **E. Moravveji**

But ... why is so important to consider so many stars?

... but massive star evolution does not only depend on mass, but also on **rotation** and **stellar winds** (+ in **binary systems**, **mass/angular momentum transfer** and the occurrence of **merger events**)

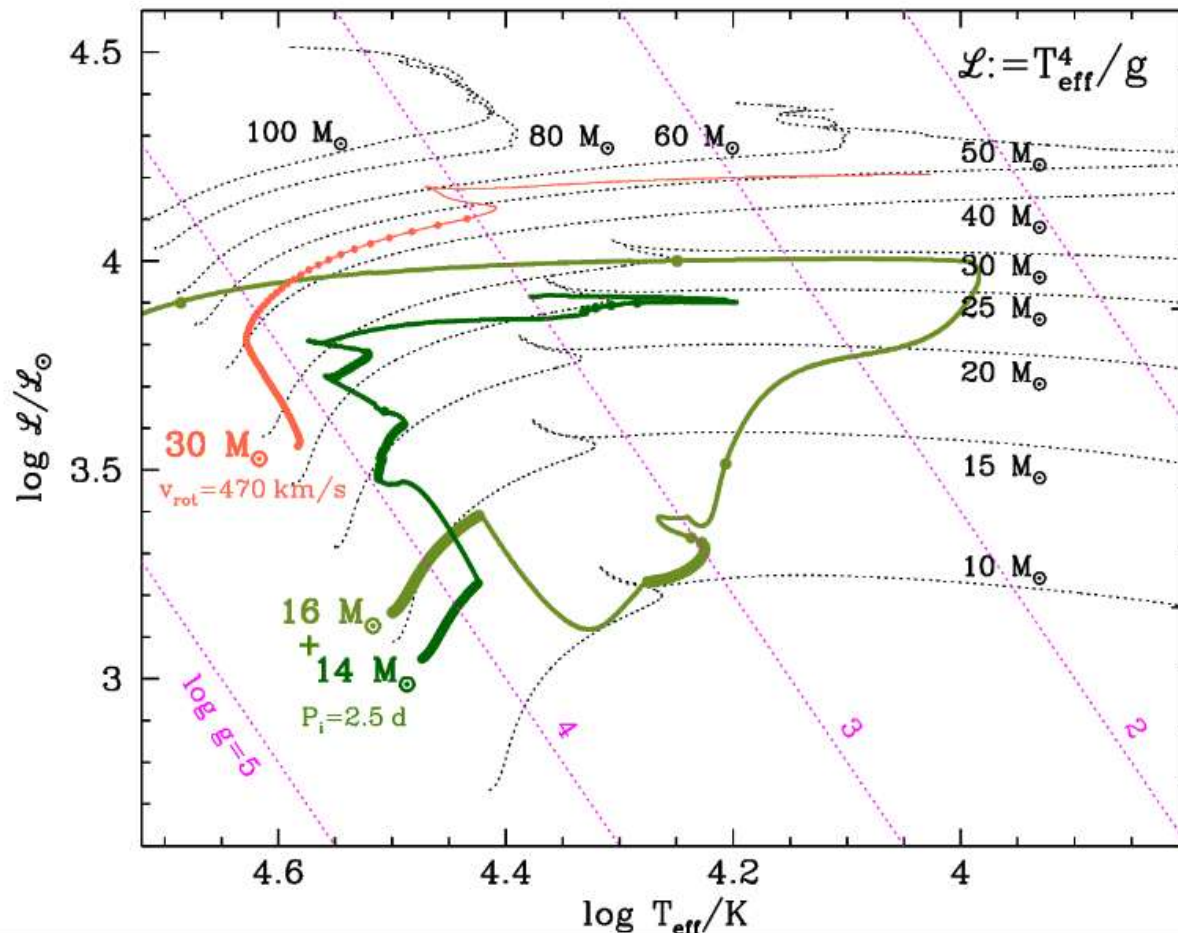

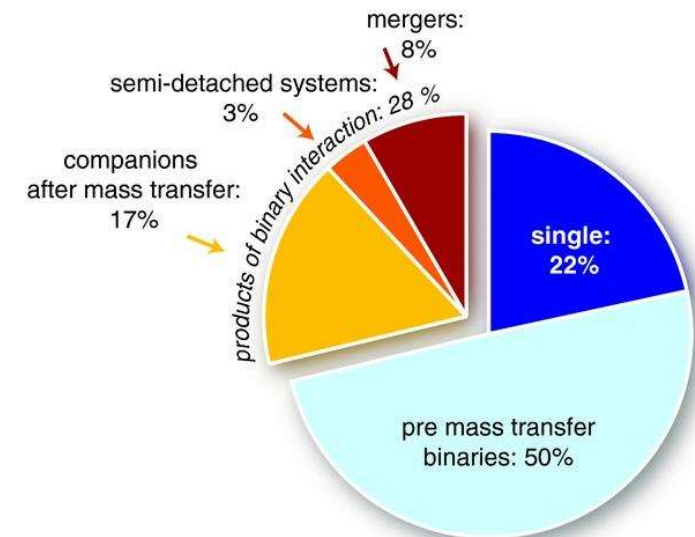

Image extracted from *Langer & Kudritzki (2014)*

Note 3: More than 70% of all massive stars is predicted to **exchange mass** with a companion along their life (*Sana et al. 2012*); in particular 30% will do during the Main Sequence (*de Mink et al. 2014*)

Note 4: The incidence of stellar **mergers** during the Main Sequence is predicted to be 8% (*de Mink et al. 2014*)

de Mink et al. (2014)

But ... why is so important to consider so many stars?

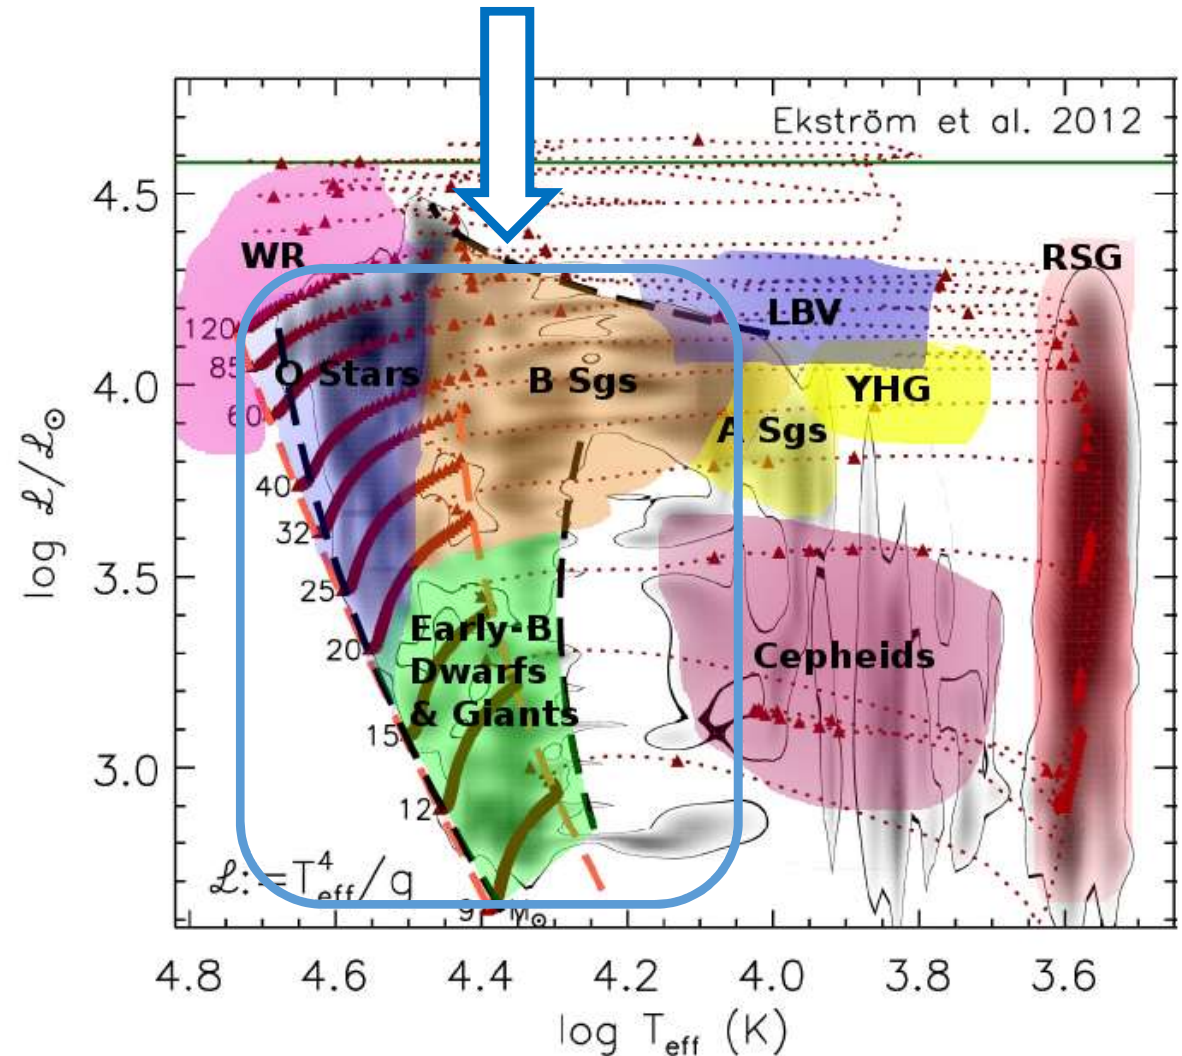

Immediate objective

Thorough empirical characterization of a **statistically meaningful sample**⁽¹⁾ of Galactic massive stars covering the full OB star domain.

⁽¹⁾ Ideally, **several thousand**

Let's try to compile as much empirical information as possible in this part of the HRD

Observations, an important pillar of the IACOB project

< 2008 – 2022+

HERMES@Mercator-1.2m

Spectroscopic observations in the IACOB project: present status

Home IACOB on the sky Technical details Acknowledgements IACOB Publications IACOB project website

Welcome to renewed interface of the IACOB spectroscopic database!

IACOB is an ambitious long-term observational project whose main scientific goal is to provide a complete and statistically significant empirical overview of the physical properties of **Galactic massive OB-type stars**. The ultimate objective of the project is that the compiled information can be used as a strong and long-lasting anchor point for our theories of stellar atmospheres, winds, interiors and evolution of massive stars.

This is the interface to have access to the spectra compiled during more than 12 years in the framework of the IACOB project: the so-called **IACOB spectroscopic database**. While not all the spectra are publicly available yet, we quote all the compiled observations for reference purposes, The different data releases (DRx) will be conveniently announced; in the meanwhile people interested in specific (samples of) spectra can contact the PI of the project by email: [ssimon \[at\] iac.es](mailto:ssimon@iac.es).

More details about the project can be found in the [project webpage](#).

The IACOB spectroscopic database mainly comprise observations made with the FIES instrument attached to the 2.56-m [Nordic Optical Telescope](#) and the HERMES spectrograph attached to the 1.2-m [Mercator Telescope](#). See above for some technical details of the database. In future developments, we plan to also incorporate data of Southern Galactic OB stars as obtained with the FEROS instrument and gathered from the [ESO public archive](#).

Search by name Star name (Rigel, etc.)	Spectral type e.g.: B1* or O* or *V*	Data Release Any	Instrument Any	<input type="checkbox"/> Only spectra available to download <input type="checkbox"/> Only the best spectrum per star
Search by coordinates hh:mm:ss dd:mm:ss	Radius 2 arcmin	V mag range 0 to 14	Time range (HJD-2400000) Min HJD to Max HJD	<input type="button" value="Search"/>

spectra: FIES, HERMES \approx 9800+ STELLA \approx 1300+ FEROS \approx 3650 SONG \approx 22500+

SpT coverage: O2 – B9⁽¹⁾ LC coverage: V, IV, III, II, Ib, Iab, Ia, Ia⁺

stars: 1750+

On-going observations: LP (HERMES+FIES): 60n (2yr) STELLA monitoring: 200h SONG time-series

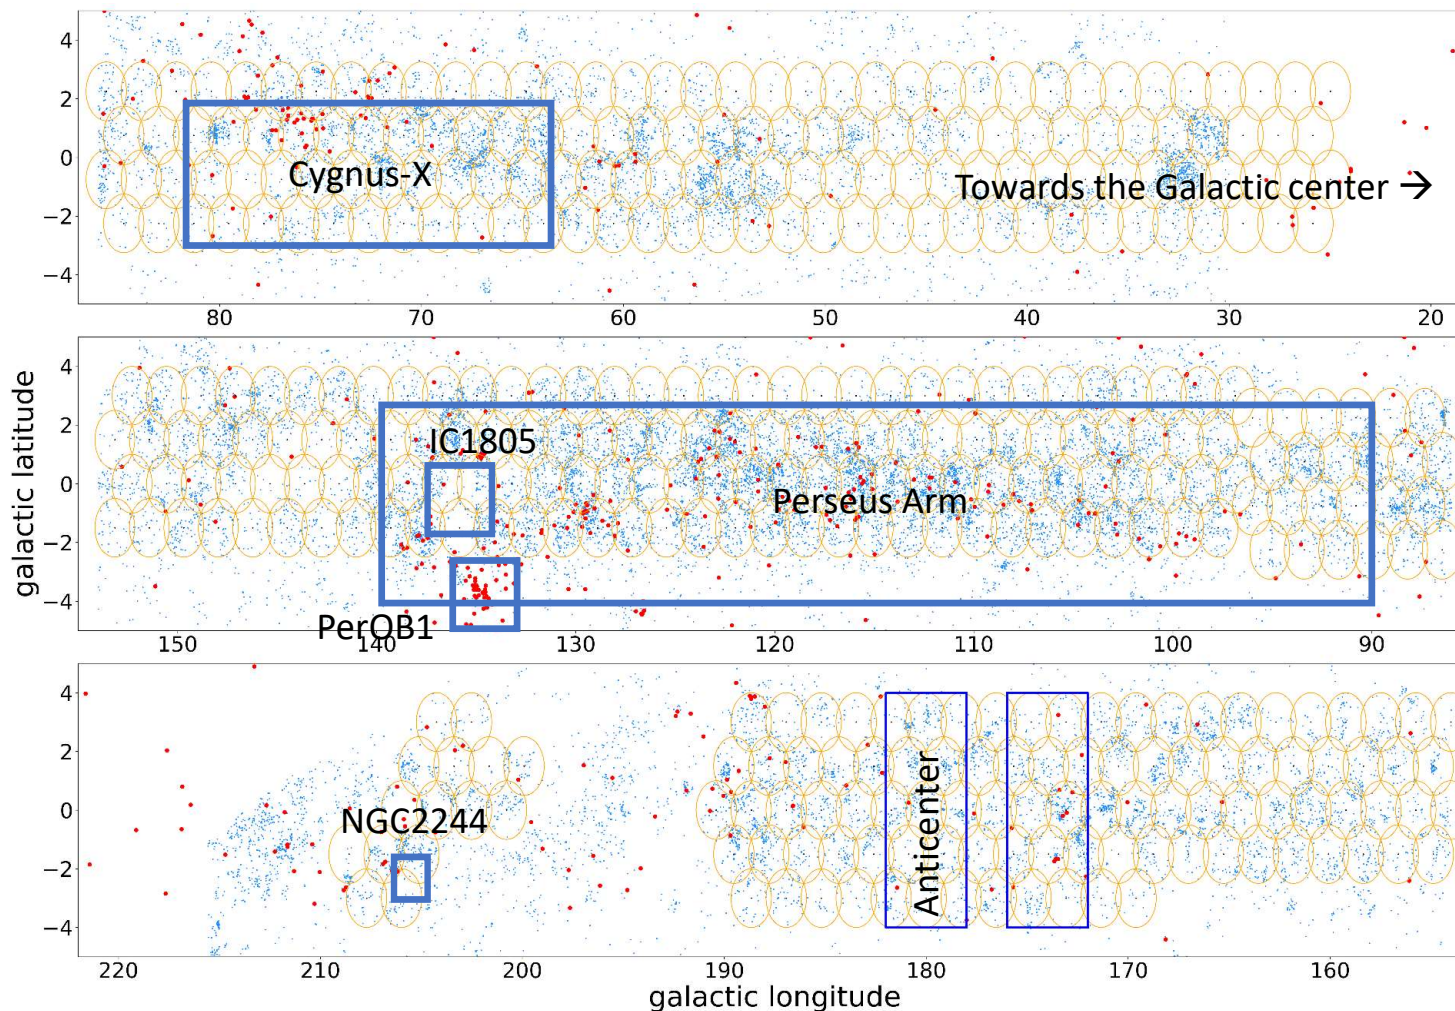

⁽¹⁾ Plus a few tens of A0-A2 Sgs

And in the next 5 years we will jump from $\sim 10^3$ to $\sim 10^4$ stars

WEAVE-SCIP (PI. Drew): An upcoming 5-year multi-object spectroscopic survey

- [1] Northern Galactic plane (R=5000, 3800-9000 Å) $\approx 5 \times 10^4$ O-B3 star candidates ($G \approx 11 - 17$)
- [2] Cygnus-X (R=20000, 4040-4650 Å + 5950-6850 Å) $\approx 5 \times 10^3$ O-B3 star candidates ($G \approx 9 - 15$)

**Were/are these (ground based)
observational efforts really needed
in the Gaia era?**

* Hopefully also **4**

The gaia view of massive OB-type stars

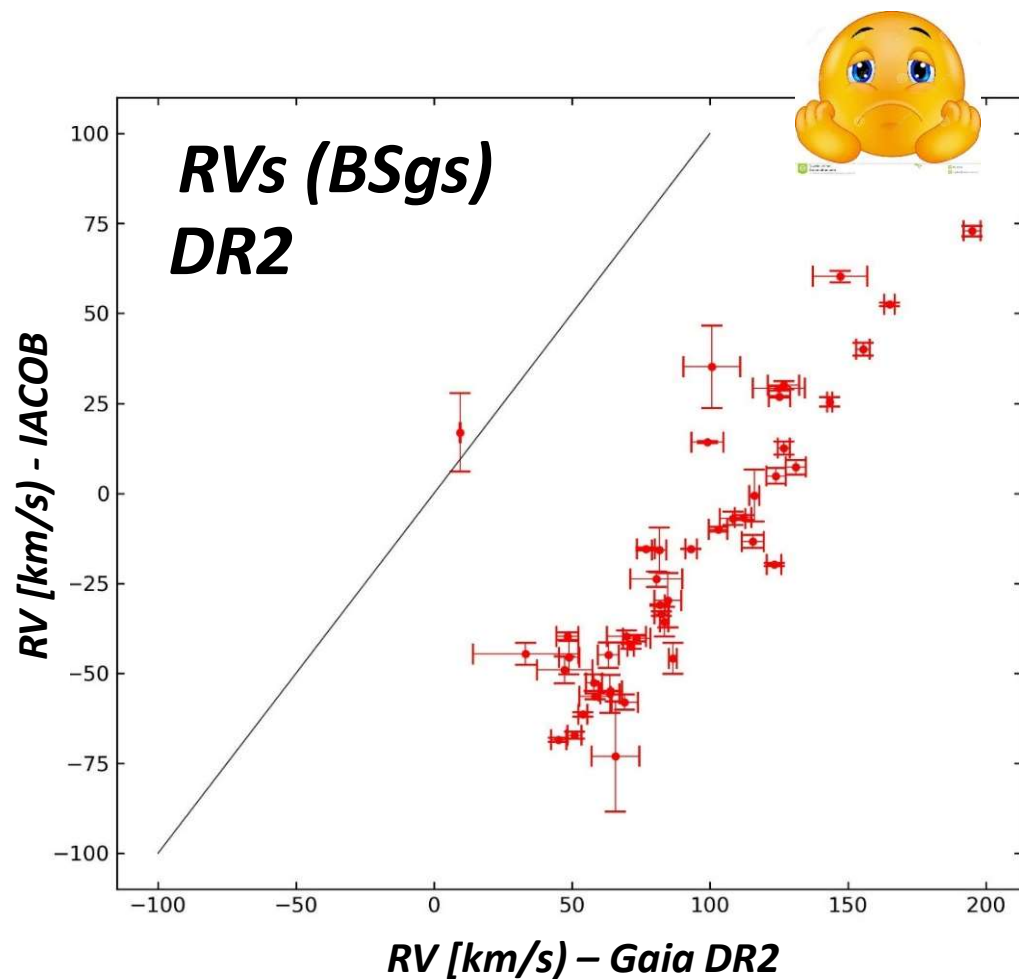

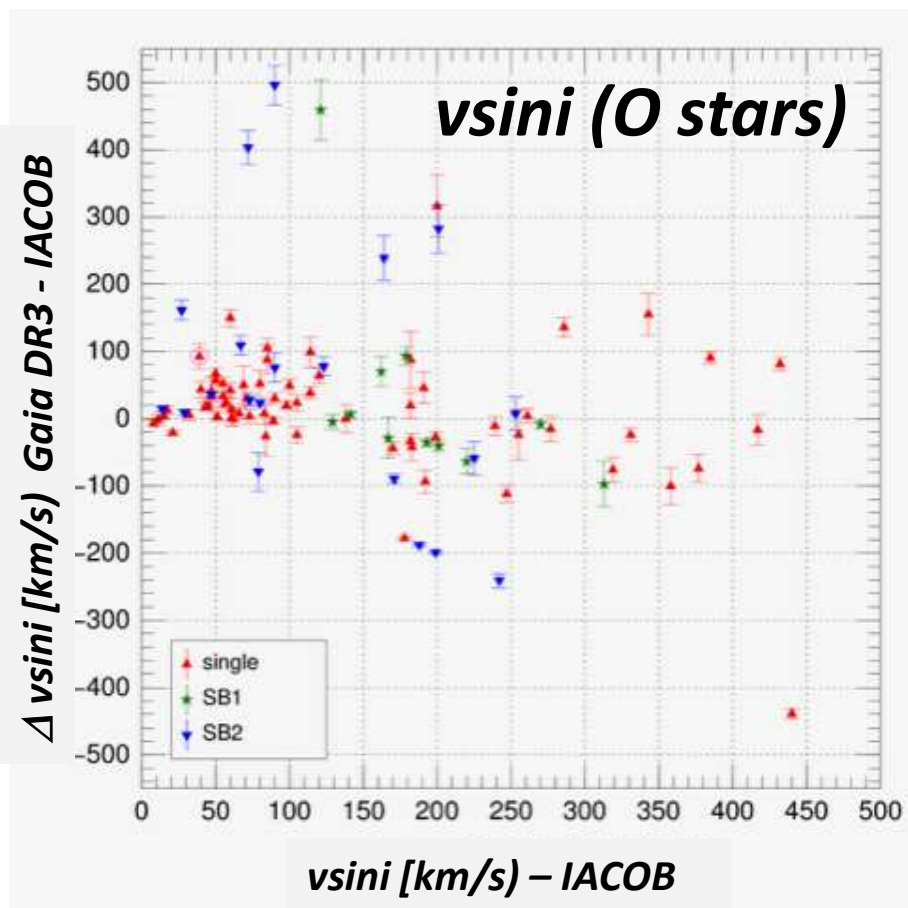

The **Gaia-RVS** range is quite boring in the case of OB stars

Optical spectroscopy is a MUST to get accurate info on:

- RV
- $v \sin i$
- Spectr. parameters
- Surface abundance

The largest sample of Galactic O-type stars spectroscopically analyzed to date

Gonzalo Holgado (PhD, ULL, 2019)

415 Galactic O stars

(70% GOSC)
2900 spectra

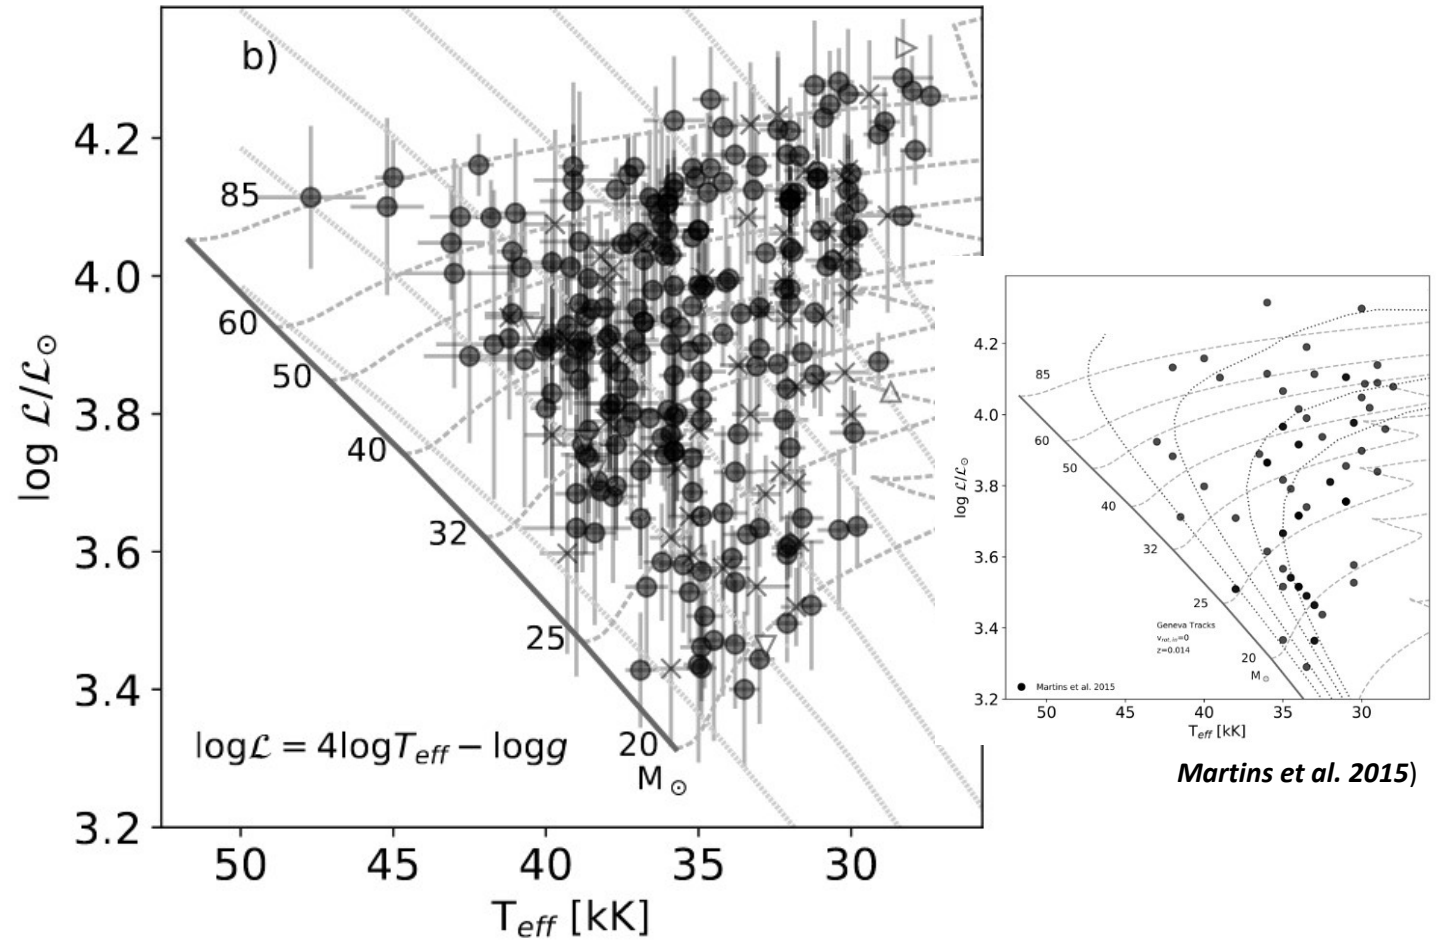

Spectroscopic binaries

59 SB1 (14%)
113 SB2 (27%)

Spectroscopic parameters⁽²⁾
(+ He abundances)

for 285 likely single and SB1 stars

Increasing the statistics⁽¹⁾ of Galactic O-type stars with spectroscopically determined parameters

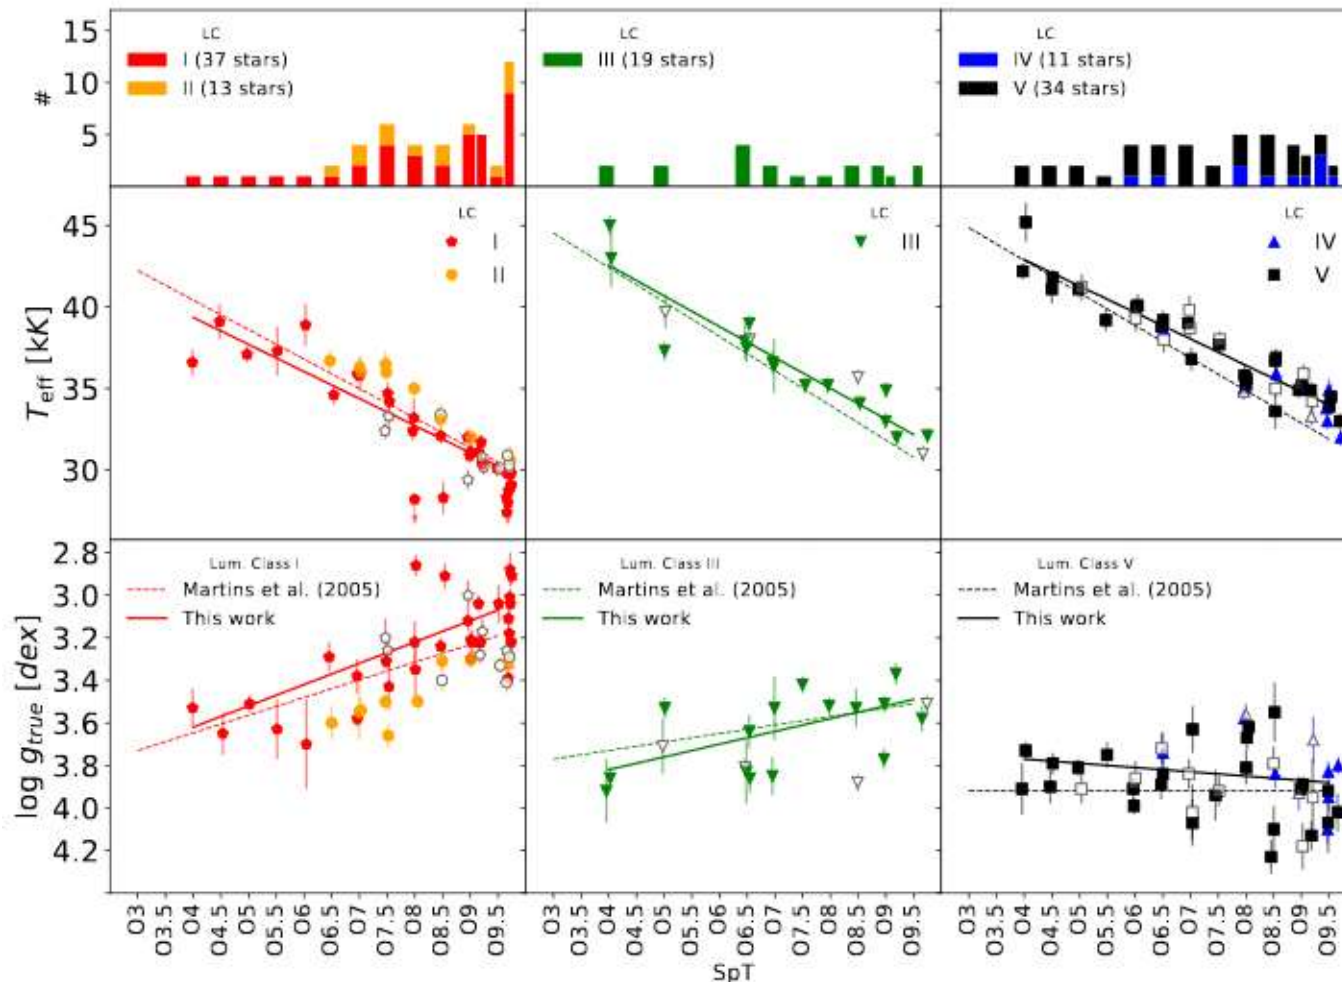

⁽¹⁾ Previous studies included no more than 70 stars (e.g., *Herrero et al. 1992, Repolust et al. 2004, Martins et al. 2015*)

⁽²⁾ Analysis tools: **IACOB-BROAD** (*Simón-Díaz & Herrero 2014*) & **IACOB-GBAT/FASTWIND** (*Simón-Díaz et al. 2012*)

The largest sample of Galactic O-type stars spectroscopically analyzed to date

Building more robust **SpT/LC – T_{eff} /logg calibrations** in Galactic O-type stars (*Holgado et al. 2018*)

128/131 O-type stars from the **GOSSS v2.0 grid of standards** for spectral classification (*Maíz Apellániz et al. 2015*)

- Larger sample
- Standards + revised SpC
- Homogeneous analysis
- Identification of SB systems

N.B.: 1216 spectra (28 SB1 + 7 SB2)

The largest sample of Galactic O-type stars spectroscopically analyzed to date

Providing stronger empirical evidence of the **dearth of O-type stars close to the ZAMS** (Holgado et al. 2020)

See also talk by G. Meynet

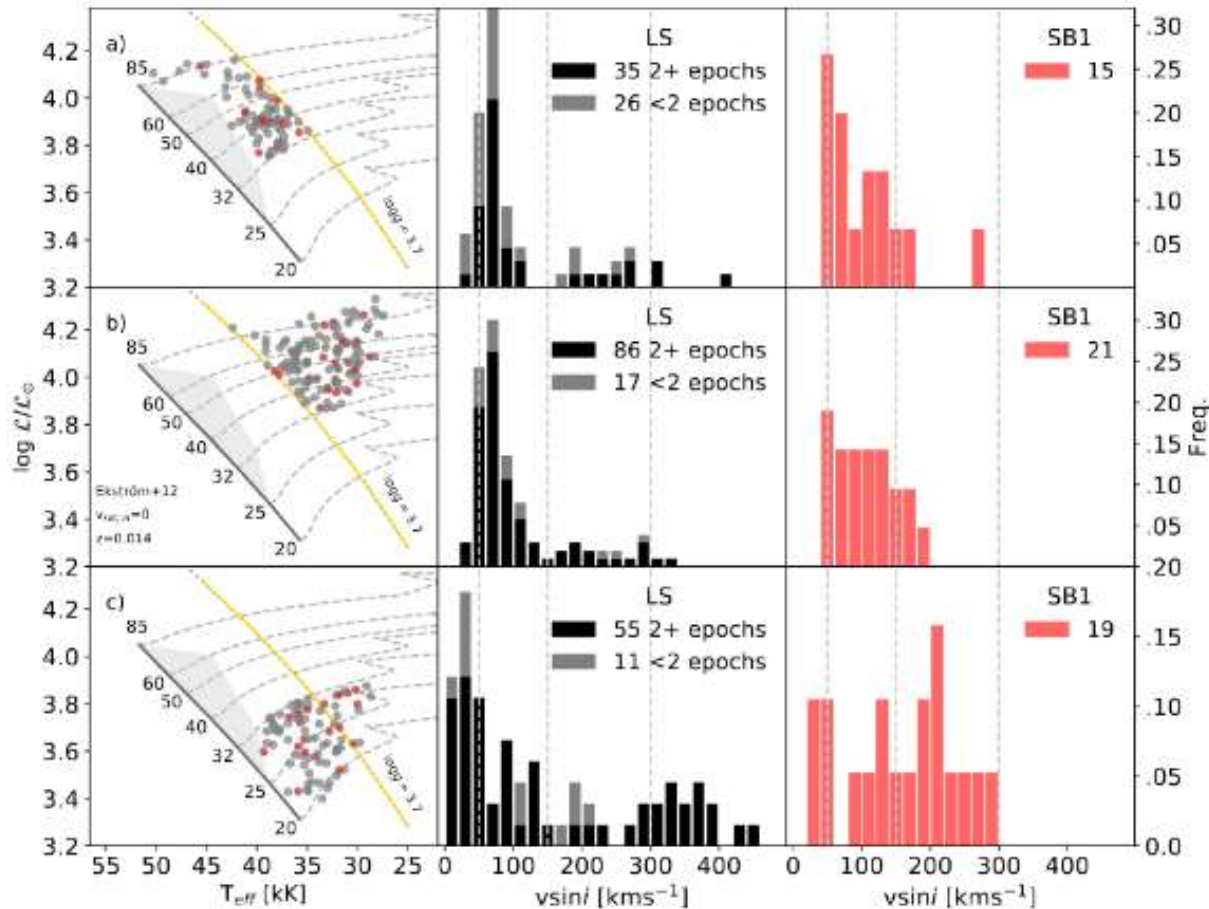

Distribution of 285 Galactic O-type stars in the sHRD (Holgado et al. 2020)

+ 2 theoretical stellar birthlines assuming a different accretion rate (Haemmerle et al. 2019)

The largest sample of Galactic O-type stars spectroscopically analyzed to date

Improving and extending further our empirical knowledge about **rotational velocities** in Galactic O-type stars ... as well as the **efficiency of internal angular momentum transport and rotational mixing**⁽¹⁾

⁽¹⁾ On the importance of rotation in massive stars: **Maeder & Meynet (2000)**

+ rotational mixing drives core processed chemical elements to the stellar surface

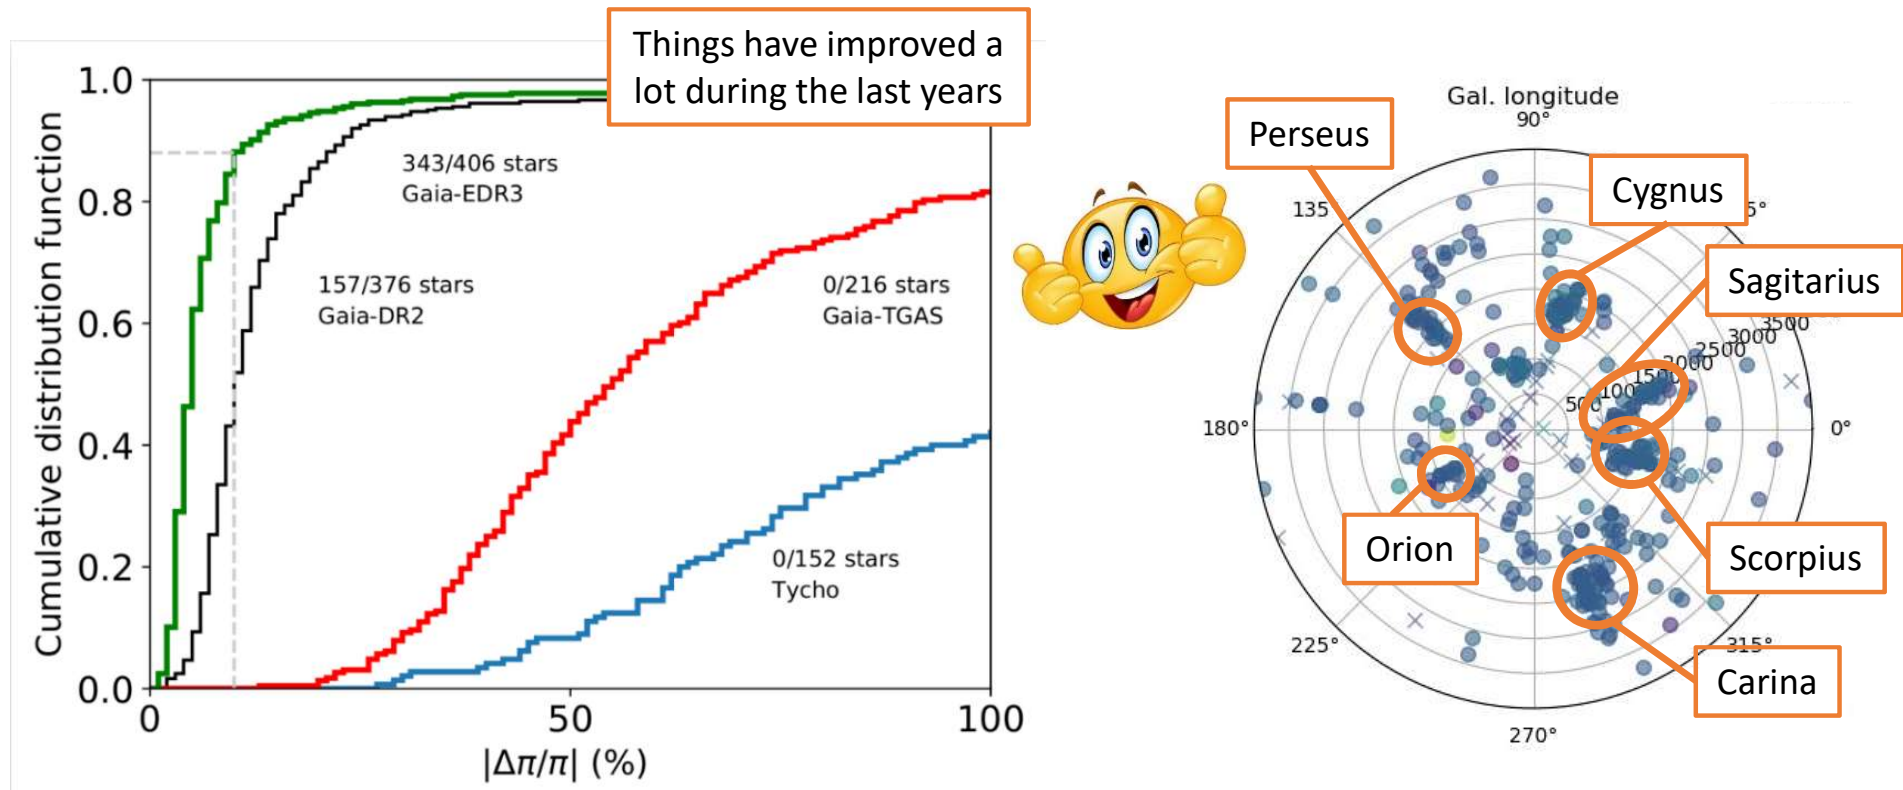

+ Next step ... He, C, N, O abundances

- **No important surface braking effect** is detected during MS evolution even for $M > 30 M_{\odot}$
- **O stars are born with less than 20% critical velocity.** Following de Mink et al. (2013, 2014), the tail of fast rotators ($vsini > 200 \text{ km/s}$, 25% of the sample) is most likely populated by mass gainers.

Parallaxes & proper motions

Having access to:

- (1) distances is critical to obtain the **fundamental stellar parameters** (R, L, M)
- (2) **kinematical** and **environmental information** is an important plus for the interpretation of results (e.g. cluster membership, runaways, ...)

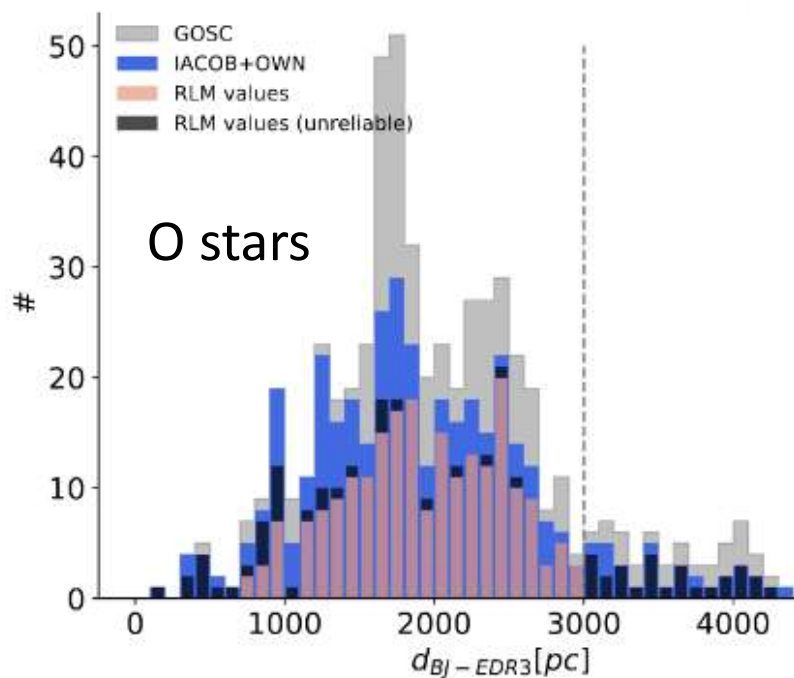

Figures from the *PhD thesis of G. Holgado (2019, Univ. La Laguna)* updated with data from EDR3

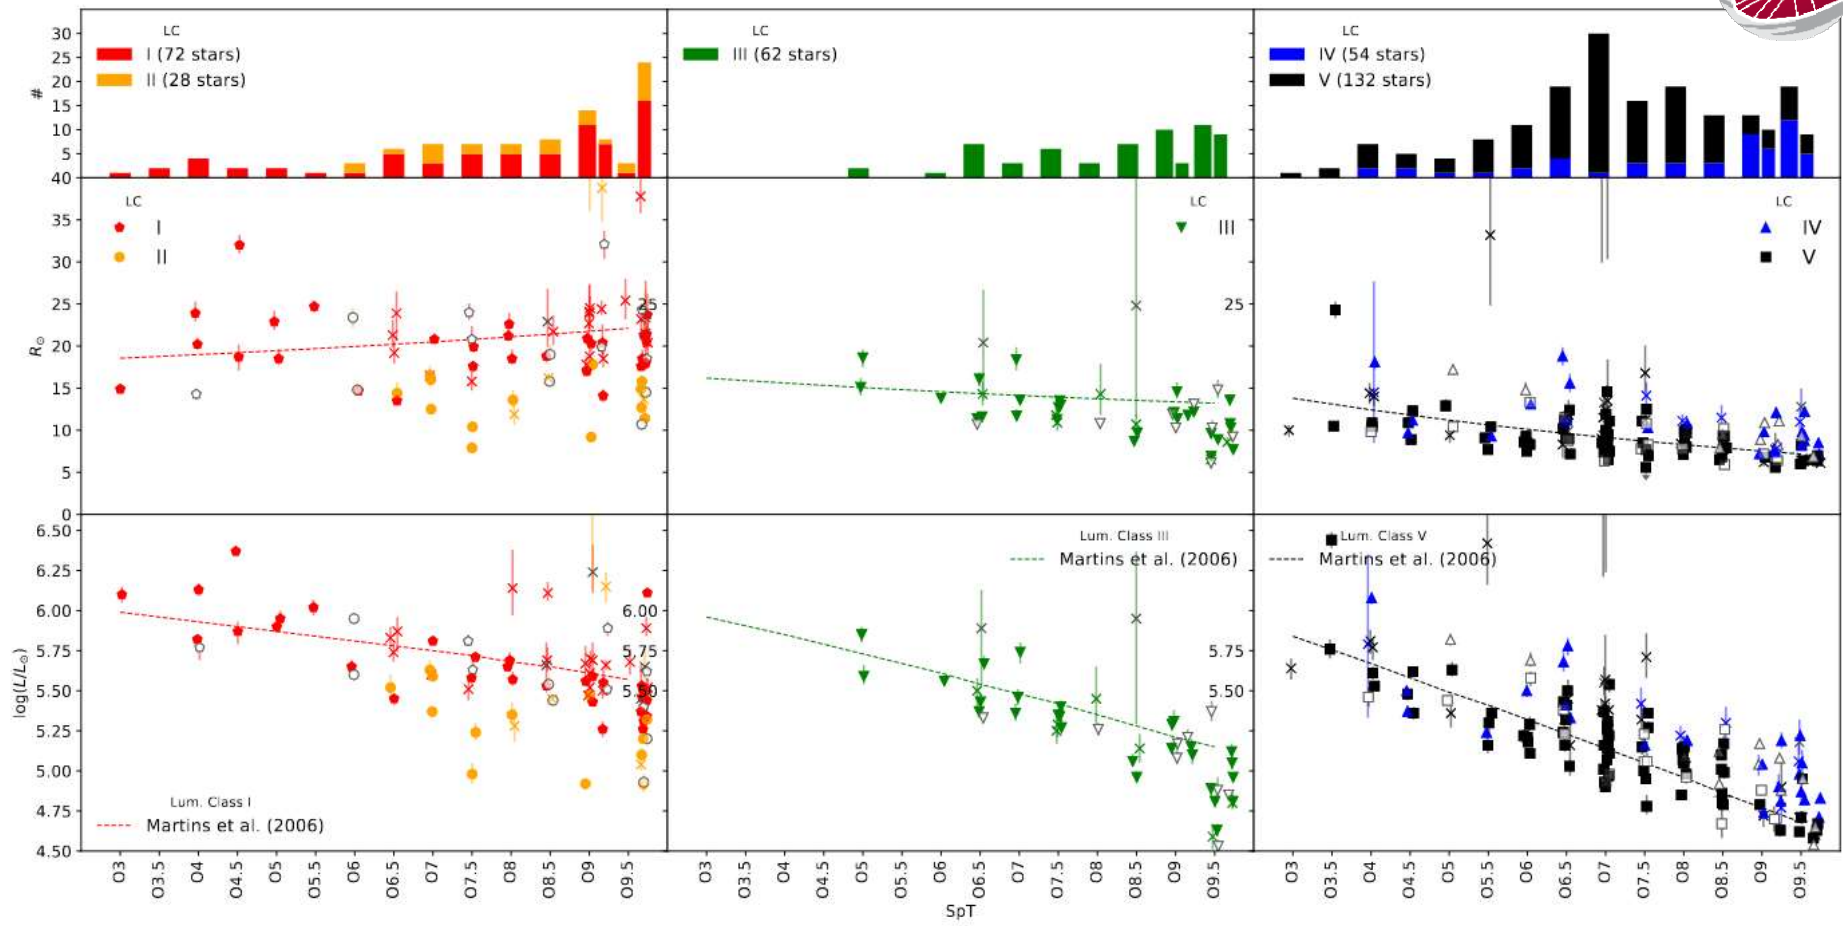

IACOB and Gaia (parallaxes: e.g. the O and B Sg samples)

Are all fast rotators the products of binary interaction?

(Britavskiy et al., *subm.*)

	Slow (365)	Fast (50)
SB2	≈ 25 %	≈ 1 %
SB1	≈ 10-20 %	≈ 10-20 %
LS	≈ 55-60 %	≈ 75-80 %
RW	≈ 20-30 %	≈ 35-50 %

More than 70% of the fast rotating O-type stars detected as LS are also runaways

Jumping to the B supergiant domain (they shouldn't be there!)

Abel de Burgos (PhD thesis, started Oct. 2019)

On the evolutionary nature of massive B-type Sgs: a modern empirical reappraisal using data from IACOB, Gaia and TESS

- \approx 700 Galactic B-Sgs
- > 4500 high-resolution spectra
- SB and LPV detection
- Spectroscopic parameters and surface abundances
- Gaia astrometry + TESS variability

IX. New empirical constraints for 700 BSGs within 12–85 M_{\odot} range

de Burgos, A.^{1,2}, Simón-Díaz, S.^{1,2}, Urbaneja, M. A.³, and a few Others

First paper in prep.

Despite not being its main scientific objective TESS is delivering

- high-cadence (2 & 30 min)
- high-precision (at μmag)

light curves for several thousands of OB stars with a minimum time-span of 27 days

But the identification and physical characterization of the OB stars cannot be done with the light curves alone. Having access to optical spectroscopy is a MUST for it

TESS is definitely opening the doors to the interior of high-mass OB-type stars

Examples of photometric variability of OB stars in TESS sectors 1-13 (BursSENS et al. 2020)

Most important origins of the photometric variability which is being detected in the TESS LCs of OB-type stars:

- **Stellar oscillations**
 - Heat driven modes
 - Internal gravity waves
- **Eclipsing binaries**
- **Rotational modulation**
 - Spots
 - Stellar winds
 - Circumstellar discs
 - Magnetospheres

Variability of OB stars from TESS southern Sectors 1–13 and high-resolution IACOB and OWN spectroscopy★

S. Burssens¹, S. Simón-Díaz^{2,3}, D. M. Bowman¹, G. Holgado^{2,3,4}, M. Michielsen¹, A. de Burgos^{2,3,5}, N. Castro⁶, R. H. Barbá⁷, and C. Aerts^{1,8,9}

- (1) Gaia revolution will certainly have an impact on our understanding of massive star evolution (parallaxes, proper motions, detection of EB and Evs).

BUT

- (2) Contrarily to the case of FGK-star, making progress in massive star evolution with Gaia requires to have access to ground-based spectroscopic support.

FORTUNATELY

- (3) ... we've put a lot of efforts in the last 15 years to make this a reality (and we will keep going for at least 5-10 years more).

STAY TUNED, BECAUSE ...

- (4) ... the IACOB project (with the aid of Gaia, TESS and WEAVE) is helping to produce and updated (more realistic) view of massive star evolution
