SCIENTIFIC CHALLENGES FOR THE NEXT DECADES

Multi-Messenger Astronomy

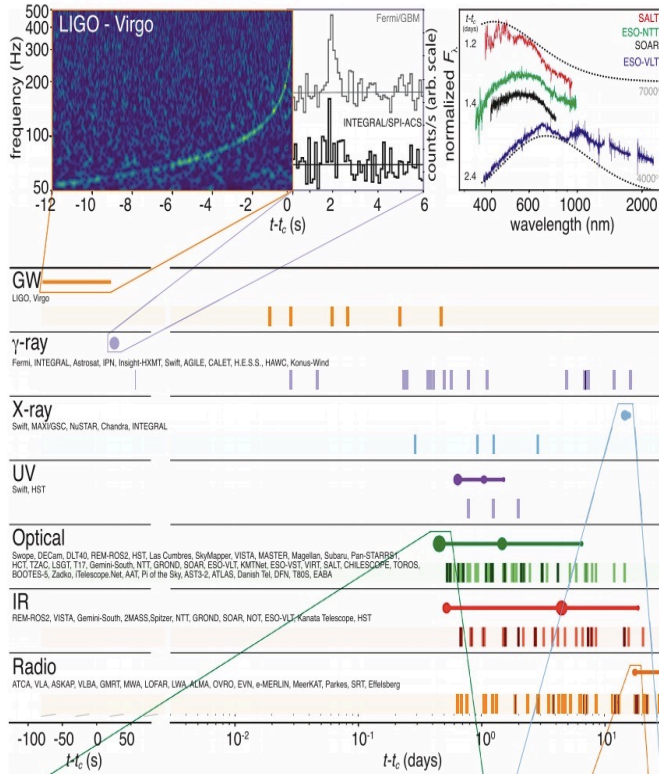

Testing Quantum Gravity

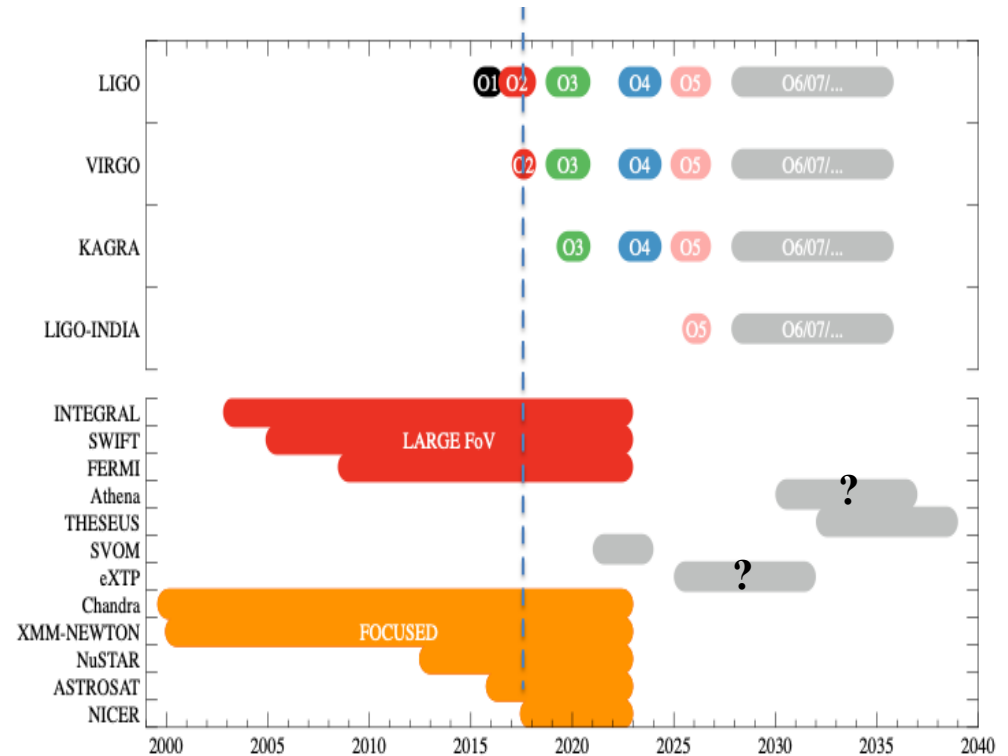

Development of Multi-messenger astronomy

GW/GRB 170817

Multi-Messenger Astronomy Paradox

We need a high-energy All-sky Monitor with large area to allow Multi-Messenger Astronomy to develop from infancy to maturity!

Monte-Carlo simulations of a true long GRB

Template (1ms resolution) of a long GRB (derived from GRB130502327 observed by Fermi GBM)

$\Delta t = 40$ s; $\phi_{\text{GRB}} = 6.5$ phot/s/cm²; $\phi_{\text{BCK}} = 2.8$ phot/s/cm²; variability ≈ 5 ms;
(Long and Short GRB with millisecond time variability, 40% of bright)

zoom of 10 ms of template
centered at the main peak
(≈ 5 ms width)

Accuracy in delays from cross-correlation analysis

Accuracy in determining delays from a bright long GRB with

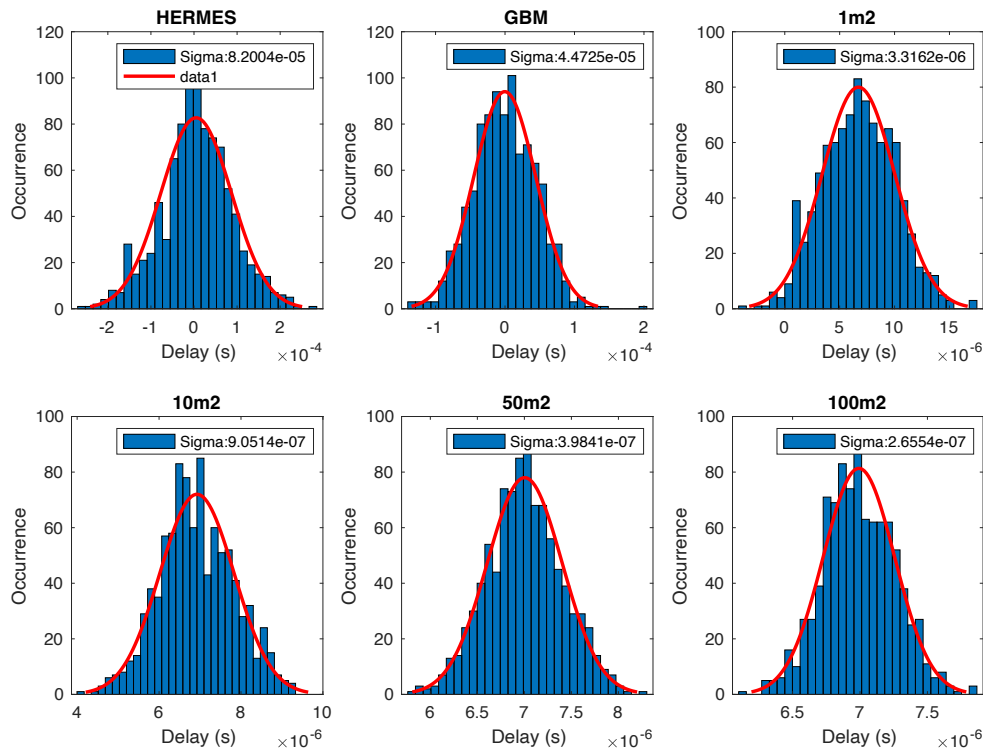

$\Delta t = 40$ s;

$\phi_{\text{GRB}} = 6.5$ phot/s/cm²;

$\phi_{\text{BCK}} = 2.8$ phot/s/cm²;

variability timescale ≈ 5 ms;

1000 pair of Monte-Carlo simulations for detectors of different effective areas A

Best fit formula:

$$\sigma_{\text{DELAYS}} \approx \sigma_{\text{ToA}} = 3.3 \mu\text{s} \times (A/1 \text{ m}^2)^{-0.58}$$

GW Triangulation & EM counterparts (Fermi GBM, INTEGRAL, HERMES Pathfinder)

Example:

long bright GRB

6.5 phot/s/cm² (source)

3 phot/s/cm² (background)

30 s duration

50-300 keV band

3 satellites each of
effective area: 50 cm²

$\sigma_{\text{ToA}} \approx 1$ ms

$\langle \text{baseline} \rangle \approx 6000$ km

positional accuracy: 3 deg

Quantum Gravity

Minimal Length Hypotesis, LIV and Dispersion Relation for photons *in vacuo*

Existence of a Minimal Length (String theories, etc.)

$$l_{\text{MIN}} \approx l_{\text{PLANCK}} = [Gh/(2\pi c^3)]^{1/2} = 1.6 \times 10^{-33} \text{ cm}$$

implies:

- i) Lorentz Invariance Violation (LIV): no further Lorentz contraction
- ii) Space has the structure of a crystal lattice and therefore
- iii) Existence of a dispersion law for photons *in vacuo*

$$|v_{\text{phot}}/c - 1| \approx \xi E_{\text{phot}}/(M_{\text{QG}} c^2)^n$$

$$\xi \approx 1$$

$n = 1, 2$ (first or second order corrections)

$$M_{\text{QG}} = \zeta m_{\text{PLANCK}} \quad (\zeta \approx 1)$$

$$m_{\text{PLANCK}} = (hc/2\pi G)^{1/2} = 21.8 \cdot 10^{-6} \text{ g}$$

First and second order Dispersion Relation for photons *in vacuo*

 (Received 5 July 2012; published 8 March 2016)

We critically discuss the measure of very short time intervals. By means of a *Gedankenexperiment*, we describe an ideal clock based on the occurrence of completely random events. Many previous thought experiments have suggested fundamental Planck-scale limits on measurements of distance and time. Here we present a new type of thought experiment, based on a different type of clock, that provide further support for the existence of such limits. We show that the minimum time interval Δt that this clock can measure scales as the inverse of its size Δr . This implies an uncertainty relation between space and time: $\Delta r \Delta t > Gh/c^4$, where G , \hbar , and c are the gravitational constant, the reduced Planck constant, and the speed of light, respectively. We outline and briefly discuss the implications of this uncertainty conjecture.

Loop Quantum Gravity (Rovelli)

First Order Dispersion Relation

$$v_{\text{phot}}/c \approx 1 - \xi E_{\text{phot}}/(M_{\text{Planck}} c^2)$$

Second Order Dispersion Relation

$$v_{\text{phot}}/c \approx 1 - \xi [E_{\text{phot}}/(M_{\text{Planck}} c^2)]^2$$

$$\xi = 1/2 \quad (\text{Burderi et. al., in preparation})$$

Dispersion Relation for photons *in vacuo* and Delays in travel time

Or "Quantum"

Accumulation of delays in light propagation:

$$\Delta t_{\text{LIV}} = \xi (D_{\text{TRAV}}/c) [\Delta E_{\text{phot}}/(M_{\text{QG}} c^2)]^n$$

The distance traveled by photons takes into account the cosmological expansion:

$$D_{\text{TRAV}}(z) = (c/H_0) \int_0^z d\beta (1+\beta) / [\Omega_\Lambda + (1+\beta)^3 \Omega_M]^{1/2}$$

z : cosmological redshift

Ω_Λ : ratio between the energy density due to the cosmological constant and the critical (closure) density of the Universe

Ω_M : ratio between the energy density due to the matter and the critical (closure) density of the Universe

The *Energy & Redshift* delay

Time lags caused by Quantum Gravity effects:

- $\propto |E_{\text{phot}}(\text{Band II}) - E_{\text{phot}}(\text{Band I})|$
- $\propto D_{\text{GRB}}(z_{\text{GRB}})$

Time lags caused by prompt emission mechanism:

- complex dependence from $E_{\text{phot}}(\text{Band II})$ and $E_{\text{phot}}(\text{Band I})$
- independent of $D_{\text{GRB}}(z_{\text{GRB}})$

GRBs & Quantum Gravity

$$\frac{dN_{\mathbf{E}}(\mathbf{E})}{dA dt} = \mathbf{F} \times \begin{cases} \left(\frac{\mathbf{E}}{\mathbf{E}_B}\right)^\alpha \exp\{-(\alpha - \beta)\mathbf{E}/\mathbf{E}_B\}, & \mathbf{E} \leq \mathbf{E}_B, \\ \left(\frac{\mathbf{E}}{\mathbf{E}_B}\right)^\beta \exp\{-(\alpha - \beta)\}, & \mathbf{E} \geq \mathbf{E}_B. \end{cases}$$

$$\sigma_{CC} \approx 0.46 \mu\text{sec} \times (2.6 \cdot 10^8/N)^{0.5}$$

$$\Delta t_{\text{MP/LIV}} = \xi (D_{\text{TRAV}}/c) [\Delta E_{\text{phot}}/(M_{\text{QG}} c^2)]^n$$

$$D_{\text{TRAV}}(z) = (c/H_0) \int_0^z d\beta (1+\beta) / [\Omega_\Lambda + (1+\beta)^3 \Omega_M]^{1/2}$$

Bright Long GRB: 8.00 (0.86 BCK) c/s (50 ÷ 300 keV) – $\Delta t = 25$ s
 Spectral shape: *Band* function with $\alpha = -1$, $\beta = -2.5 \div -2.0$, $E_B = 225$ keV
 Detector effective area: $A = 100$ m²

Accuracy in cross-correlation in function of the number of photons: $E_{CC}(N) = 0.46 \mu\text{s} \sqrt{2.6 \cdot 10^8/N}$
 Λ CDM cosmology: $\Omega_\Lambda = 0.6911$ and $\Omega_{\text{Matter}} = 0.3089$

Search for a first order Dispersion Relation in a sample of GRBs of known redshift (Burderi *et al.* Exp. Astr., 2021)

Accumulation of delays in light propagation:

$$\Delta t_{\text{LIV}} = \xi (D_{\text{TRAV}}/c) [\Delta E_{\text{phot}}/(M_{\text{QG}} c^2)]^n$$

For a sample of $i = 1 \dots N$ GRB of known redshift z_i at a given energy E , adopt:

$$n = 1; D_{\text{TRAV}}/c = \tau_0 f(z); M_{\text{QG}} = \zeta m_{\text{PLANCK}}; \Delta E_{\text{phot}} = E - E_0$$

$\tau(E)$ = intrinsic spectral delay at E ; $\xi/\zeta = \alpha(E) \approx 1$ = delay constant at E

$$\tau_0 = 1/H_0$$

$$f(z_i) = \int_0^z d\beta (1+\beta)/[\Omega_\Lambda + (1+\beta)^3 \Omega_M]^{1/2}$$

Thus we have:

$$\Delta t_i = \tau(E) + \tau_0 f(z_i) \times \alpha(E) (E - E_0) / (m_{\text{PLANCK}} c^2)$$

Plot Δt_i vs. $t_i = \tau_0 f(z_i) (E - E_0) / (m_{\text{PLANCK}} c^2)$ and fit with

$$\Delta t_i = \tau(E) + \alpha(E) \times t_i \text{ to obtain } \tau(E) \text{ and } \alpha(E)$$

If a first order dispersion relation is present, $\alpha(E) = \alpha$ for any energy E

Compute the average value of $\alpha(E)$ and its standard deviation: $\alpha = \langle \alpha(E) \rangle$ and σ_α , for all the energy considered,

Or "Quantum Loops"?

Quantum Foam?

quantum foam?

Macroscopic

Search for a first order Dispersion Relation in a sample of GRBs of known redshift

Since all the errors are of statistical origin, the accuracy of the method depend on the number of photons detected.

If the the delays are detectable (or constrained) for $\alpha(E) \approx 1$ with **one GRB** and a detector of effective area $A = 100 \text{ m}^2$, the same number of photons and, therefore, accuracy is possible with a sample of $N = 1000$ GRBs and a detector of effective area

$$A^* = 100 \text{ m}^2/N = 100 \text{ m}^2/1000 = 10^6 \text{ cm}^2/1000 = 10^3 \text{ cm}^2$$

Or "Quantum Loops"?

Quantum Foam?

quantum foam?

Location of GRBs with fleets of satellites and redshifts

Accuracy in determining delays from Monte-Carlo simulations of 100 pairs of GRBs of fluence 260 (112 BCK) photons/cm² with detectors of different effective areas:

$$\sigma_{\text{DELAYS}} \approx \sigma_{\text{ToA}} = 3.3 \mu\text{s} \times (A/1 \text{ m}^2)^{-0.58}$$

Accuracy in determining α and δ with $N_{\text{SATELLITES}}$ ($N_{\text{IND}} = N_{\text{SATELLITES}} - 1$; $N_{\text{PAR}} = 2$):

$$\sigma_{\alpha} \approx \sigma_{\delta} = c \sigma_{\text{ToA}} / \langle \text{baseline} \rangle \times (N_{\text{IND}} - N_{\text{PAR}})^{-1/2}$$

Large fleet of small satellites in Low Earth Orbits:

$$A = 30 \times 30 \text{ cm} \approx 0.1 \text{ m}^2$$

$$\sigma_{\text{ToA}} \approx 12.5 \mu\text{s}$$

$$N_{\text{SATELLITES}} \approx 1000$$

$$\langle \text{baseline} \rangle \approx 6,000 \text{ km}$$

$$\sigma_{\alpha} \approx \sigma_{\delta} \approx 4 \text{ arcsec}$$

Three satellites with detectors of 1 m² effective area in Earth–Moon Lagrangian points:

$$A \approx 1.0 \text{ m}^2$$

$$\sigma_{\text{ToA}} \approx 3.3 \mu\text{s}$$

$$N_{\text{SATELLITES}} = 3$$

$$\langle \text{baseline} \rangle \approx 400,000 \text{ km}$$

$$\sigma_{\alpha} \approx \sigma_{\delta} \approx 0.5 \text{ arcsec}$$

Three satellites with detectors of 400 cm² effective area in *Cart-wheel* orbits:

$$A \approx 1.0 \text{ m}^2$$

$$\sigma_{\text{ToA}} \approx 21.3 \mu\text{s}$$

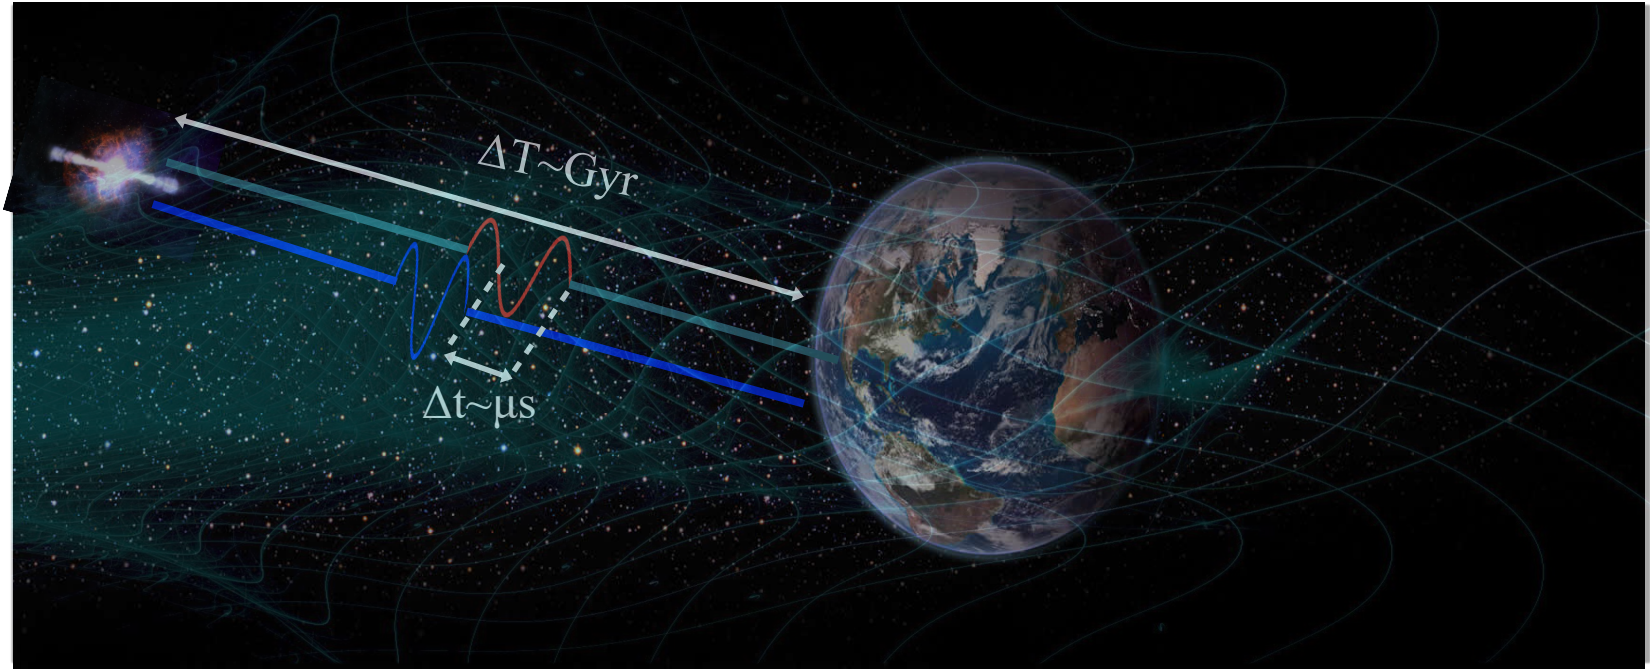

$$N_{\text{SATELLITES}} = 3$$

$$\langle \text{baseline} \rangle \approx 2,500,000 \text{ km}$$

$$\sigma_{\alpha} \approx \sigma_{\delta} \approx 0.5 \text{ arcsec}$$

Once the position is known, the redshift of the GRB host galaxy is obtained through pointed observations of large optical telescopes.

GrailQuest: First Quantum-Gravity dedicated experiment

Robust Quantum Gravity Experiment to:

- i) Search for a Dispersion law for photons $v_{\text{ph}}/c \sim [1 - l_P/\lambda_{\text{ph}}]$
- ii) Explore Space–Time Granular structure down to $l_P \sim 10^{-33}$ cm

Performed by means of a Constellation of 100÷10000 small sats with:

- i) Total collecting area: $\sim 100 \text{ m}^2$
- ii) Energy band: 50 keV – 50 MeV
- iii) Time resolution: $< 0.1 \mu\text{s}$

The *ALBATROS* mission: cart-wheel orbits

3 satellites in “Cart-wheel” orbits (e.g., LISA orbits):

- 3 heliocentric orbits with $a=1\text{AU}$
- 3 slightly different small inclinations (idegrees) w.r.t. to ecliptic plane
- Equatorial triangle of side $D\ 2.5\ 10^6\ \text{km}$
- Contact to ground up to 23 hours per day
- Wet mass $\sim 230\ \text{kg}$ per satellite
- Dry mass $\sim 165\ \text{kg}$ per satellite

Astonishingly
Long
Baseline
Array
Transient
Reconnaissance
Observatory from
Space

The *ALBATROS* mission

Three satellites in “*Cart-wheel*” orbits:
 3 heliocentric orbits with $a = 1\text{AU}$ and 3 slightly different small inclinations ($i \approx 0.5^\circ$) w.r.t. the ecliptic plane: equilateral triangle of side $D \approx 2.5 \cdot 10^6 \text{ km}$.

Two 400 cm^2 effective area detectors (HERMES like) per satellite pointing in opposite directions w.r.t. the equilateral triangle plane.
 FoV: 4π steradians (whole sky)

Detection rate: $1 \div 2$ GRB/day

Positional accuracy with Temporal Triangulation Techniques:

$\sigma_\alpha \approx \sigma_\delta \approx c \sigma_{\Delta t} / B \approx 24 \text{ arc-sec} \times (B/2.5 \times 10^6 \text{ km})^{-1} \times (\sigma_{\Delta t}/1\text{ms})$ implies: $\sigma_\alpha \approx \sigma_\delta \approx 0.5 \text{ arc-sec}$ for 400 cm^2 detectors

Prompt follow-up with ground-based optical telescopes:
 75% success in determination of redshift z

Number of GRB with determined redshift detected in 4 yr nominal mission lifetime $N \approx 1000$

Effective constrain of first order (LIV) Quantum Gravity dispersion law for photons
