# Towards Image Synthesis with Photon Counting Stellar Intensity Interferometry

Status Update 27 March 2024

**SPIE.** PHOTONICS  
EUROPE

# Unconventional Optical Imaging IV

## Stellar Intensity Interferometry (SII)

### How it works?

Fast correlated variability is produced by pairs of point at the source ( $P_1, P_2$ ). Each point radiates and is independent of each other.

SII is based on a measurement of the correlation of the light intensity fluctuations of a star detected at two or more telescopes.

Fig.1: Working principle of an intensity interferometer. From [1].

### What can we measure?

Radius and surface structures of bright and hot stars (O/B → F/G type).

## Towards Image Synthesis with Photon Counting Stellar Intensity Interferometry

### The first Intensity Interferometer

SII was pioneered by **Brown & Twiss** in Narrabri, Australia [2]. They made the first direct astronomical measure of stellar radii via SII.

Fig.2: The two Narrabri SII telescopes.

Operating simultaneously ARRAY of large area telescopes  
+ connecting them electronically → renewed interest for SII  
→ Tool for imaging obs. in optical band  
(~long-baseline [radio] interferometric array).

## ASTRI Mini Array [3]

9 Imaging Atmospheric Cherenkov Telescopes to:

- study gamma-ray sources at very high energy (TeV)
- **perform optical SII observations** → ASTRI SII Instrument (SI<sup>3</sup>)

**Goal:** using the **long multiple baselines (36)** of all 9 telescopes to do image reconstruction with resolution of **~100  $\mu$ as**. [4]

SI<sup>3</sup> => optical window (1-8 nm centered at 420-500 nm).

## METHODS

### Photon-Counting Intensity Interferometry

Counting coincidences in photon arrival times measured at 2 telescopes and exploiting the quantum properties of the light emitted from a star.

#### 2<sup>nd</sup> order (discrete) degree of coherence of a star [5]

Measures the degree of correlation [of its lights].

Depends on telescopes separations  $d$  and the relative delay  $\tau$  between them.

$$g^{(2)}(\tau, d) = \frac{N_{XY} N}{N_X N_Y}$$

$N_X, N_Y$  = # photons detected at telescopes X and Y in time T

$N_{XY}$  = # simultaneous detection in bin  $dt$

$N$  = # intervals (T/dt)

#### ASIAGO SII experiment

TEST

1.22m Galileo (IFI+lqueye) + 1.82m Copernico (Aqueye+) Telescopes @Asiago (Italy).

#### Goal

- First measurements of the correlation of the arrival times of photons from a star counting coincidences in post-processing.
- Validating the feasibility of this type of measurements on a km baseline

The Aqueye/lqueye team!

Scan me!

## Computational Time to analyze SII data

To analyze 1 hr of data

(36 baseline):

$10^4$  hr (CPU time) →

$10^4/2000$  core = 5 hr

→  $5 \cdot 24$  hr (real data) = 5 days

## IMAGES Synthesis

1<sup>st</sup>

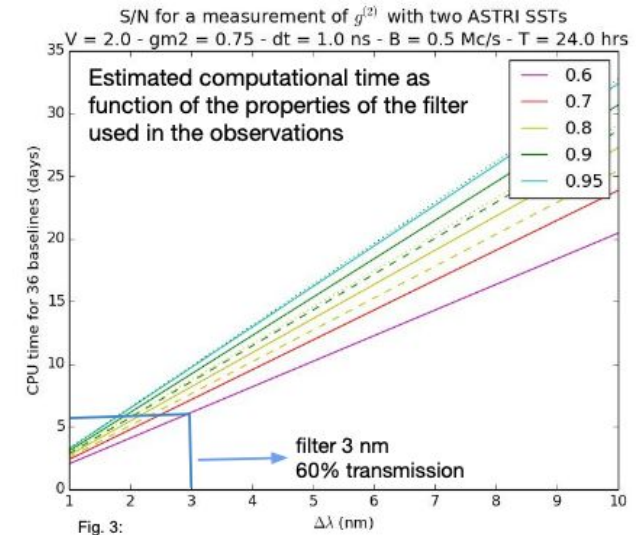

Optimization of the available pipelines for the treatment of the time series acquired at extremely high count rates with the entire array.

2<sup>nd</sup>

Development of efficient and innovative algorithms for the cross-correlation of the arrival times in large time series.

3<sup>rd</sup>

Implementation of a dedicated pipeline for the synthesis of images starting from the interferometric data and the data related to the instrumental simulations.

## Resources Request

Parallelize and accelerate algorithms with CUDA.

Start from **multiple CPUs** (2000 CPU cores: 1 hr data)

→ code optimized (100 hr of data)

→ **GPUs** (to accelerate the computing time: 20x).

4 Leonardo Booster GPUs (1 hr data in 1 hr).

|               | CPUs            | GPUs            |
|---------------|-----------------|-----------------|
| Tot. cores hr | $5 \times 10^6$ | $5 \times 10^5$ |
| 2024          | 70%             | 30%             |
| 2025          | 30%             | 70%             |

Table: Prospects for use of Resources.

# ASTRI SII SIMULATIONS 36 baseline

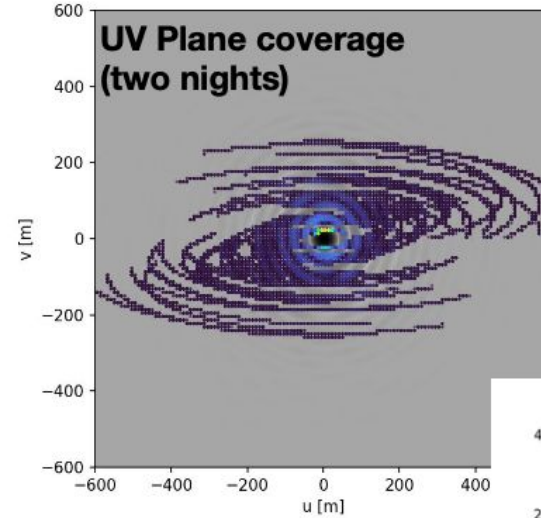

Simulated  $g^{(2)}$  measurements of two different stars with an uniform disk.

10 hr obs.

30 hr obs.

Simulated A-type star + dark spots

WORK IN PROGRESS

Thank you for the attention!
