Reference paper

Ledda S., Danielski C., Turrini D. A&A 675, A184 (2023)

The formation and long-term evolution of circumbinary
planetary systems across the H-R diagram
Florence, 14-17 January 2025

Motivations

Circumbinary discs can form around double white dwarfs (DWD)

(e.g., Kashi & Soker 2011, Passy et al. 2012)

Unexplored testing ground for current planetary formation models

Constraining the population of potentially second-generation exoplanets

(e.g., Perets H. 2010, Zorotovic & Schreiber 2013, Volschow et al. 2014)

Supporting the planetary detection science case of the Laser Interferometer Space Antenna (LISA) mission

(e.g., Danielski et al. 2019)

What we found

- High metallicity and accretion rates are crucial to form gas giant (GG) planets
- Large population of sub-Neptunian (SN) and Neptunian (N) planets
- Final planet locations mostly within 5 au from the disc centre

The disc models

- **Filling the gaps in our understanding working by analogy with pre-MS discs**
- **Time-independent**
 - Neglecting any evolution of the disc

Maximum planet-forming potential of the disc

Credits: Tanaka et al. 2020 ApJ 891, 143

The disc models

Credits: Tanaka et al. 2020 ApJ 891, 143

- **Filling the gaps in our understanding working by analogy with pre-MS discs**

- **Time-independent**

- Neglecting any evolution of the disc

Maximum planet-forming potential of the disc

- **Time-dependent**

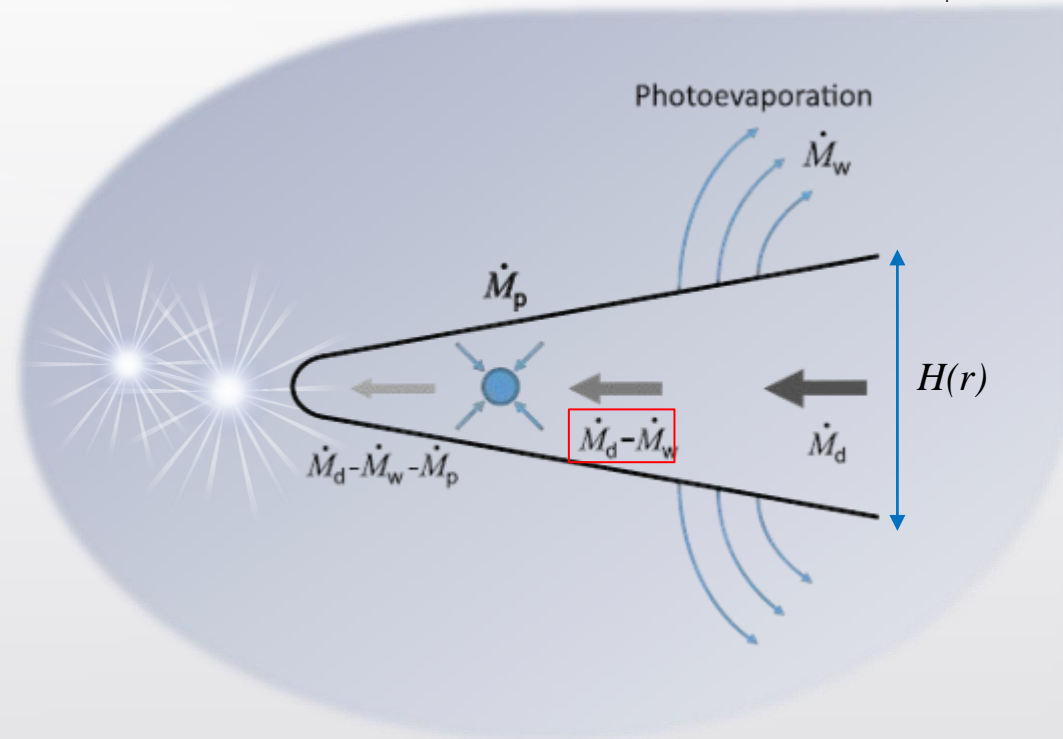

- Viscosity-driven accretion rate onto the star (\dot{M}_d)
- Photoevaporation rate ($\dot{M}_w = 10^{-8} M_\odot/\text{yr}$)

Limited disc lifetime

Time-dependent material supply to the planet-forming region

Planet formation processes

Runaway gas accretion

$$\frac{dM_p}{dt} \propto (\dot{M}_d - \dot{M}_w)$$

Gas contraction

$$\frac{dM_p}{dt} \propto M_p^{7/2}$$

Pebble accretion

$$\frac{dM_p}{dt} \propto \xi \dot{M}_d$$

Venturini, J., Ronco, M.P. & Guilera, O.M. *Space Sci Rev* **216**, 86 (2020)

Type II migration

$$\frac{dr}{dt} \propto -M_p \Sigma_{gap}$$

Type I migration

$$\frac{dr}{dt} \propto -M_p \Sigma_g (H/r)^{-2}$$

Initial formation environment

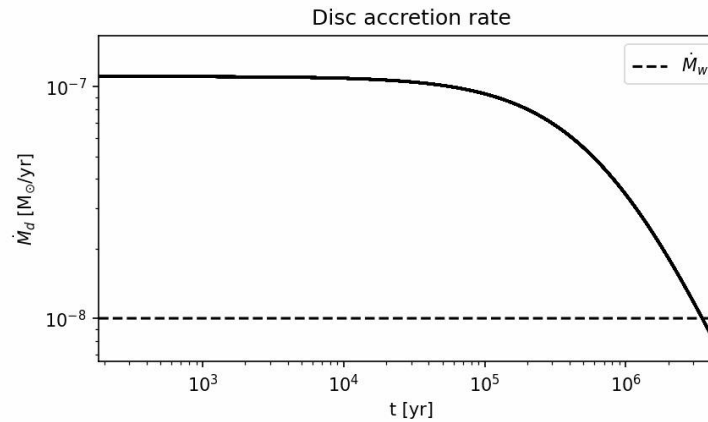

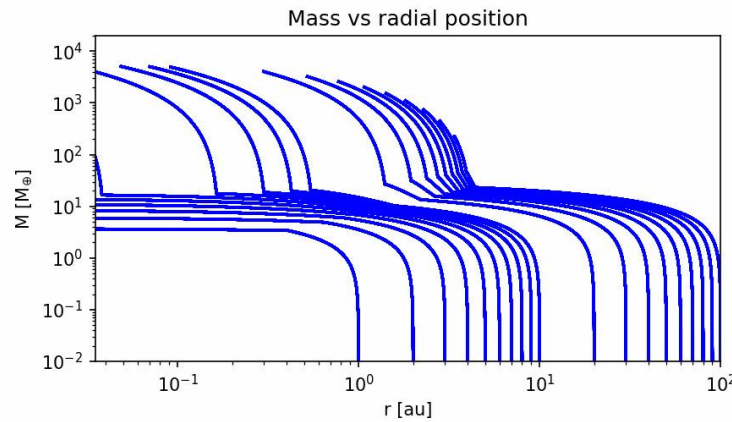

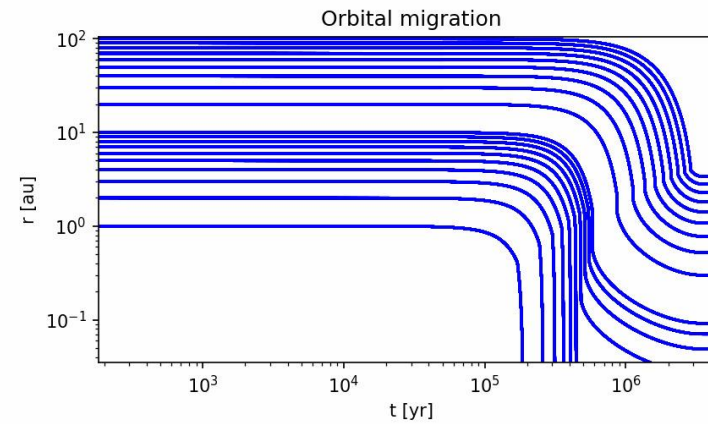

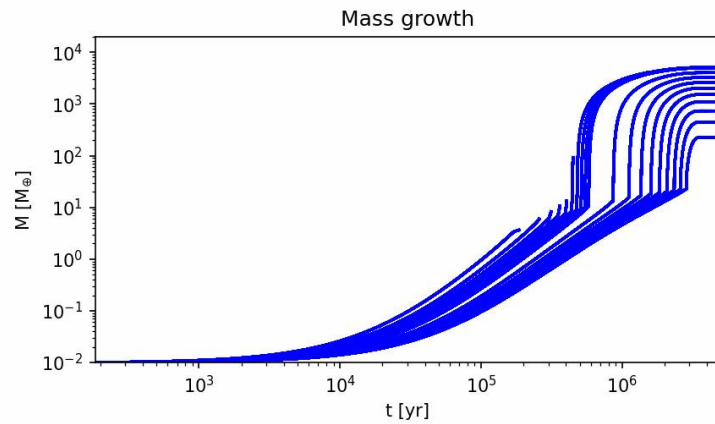

Results – Time-independent vs Time-dependent tracks

Results – Time-independent vs Time-dependent tracks

Planet formation evolution ($r_c = 150$ AU, $\xi = 0.01$, $T_{eff2} = 75000$ K) - Time (yr): 4.950×10^6

Results – Planets distribution

First-generation seeds

SNs at $t_0 = 10\tau_c$

Ns at $t_0 = 10\tau_c$

GGs at $t_0 = 10\tau_c$

Second-generation seeds

SNs at $t_0 = 0.1$ Myr

Ns at $t_0 = 0.1$ Myr

GGs at $t_0 = 0.1$ Myr

Second-generation seeds

SNs at $t_0 = 1$ Myr

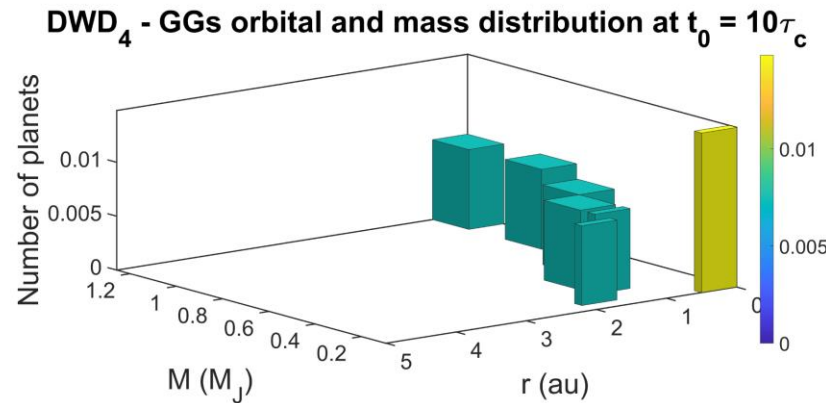

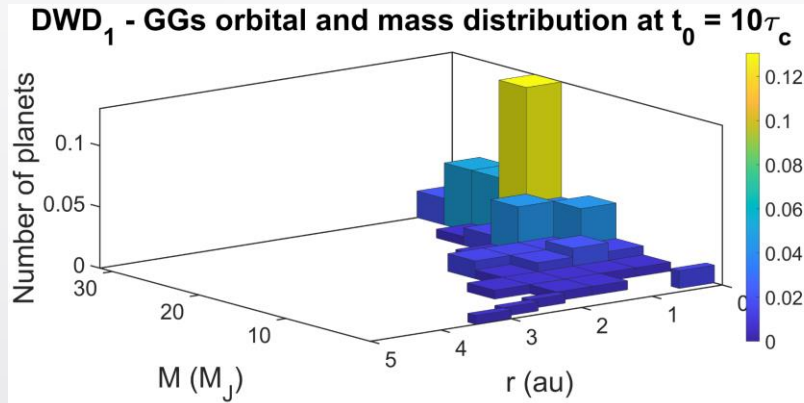

Ns at $t_0 = 1$ Myr

GGs at $t_0 = 1$ Myr

Results – Final masses and locations of GGs

Results – Body survived to the CE

$t_0 = 0.1 \text{ Myr}$

Conclusions

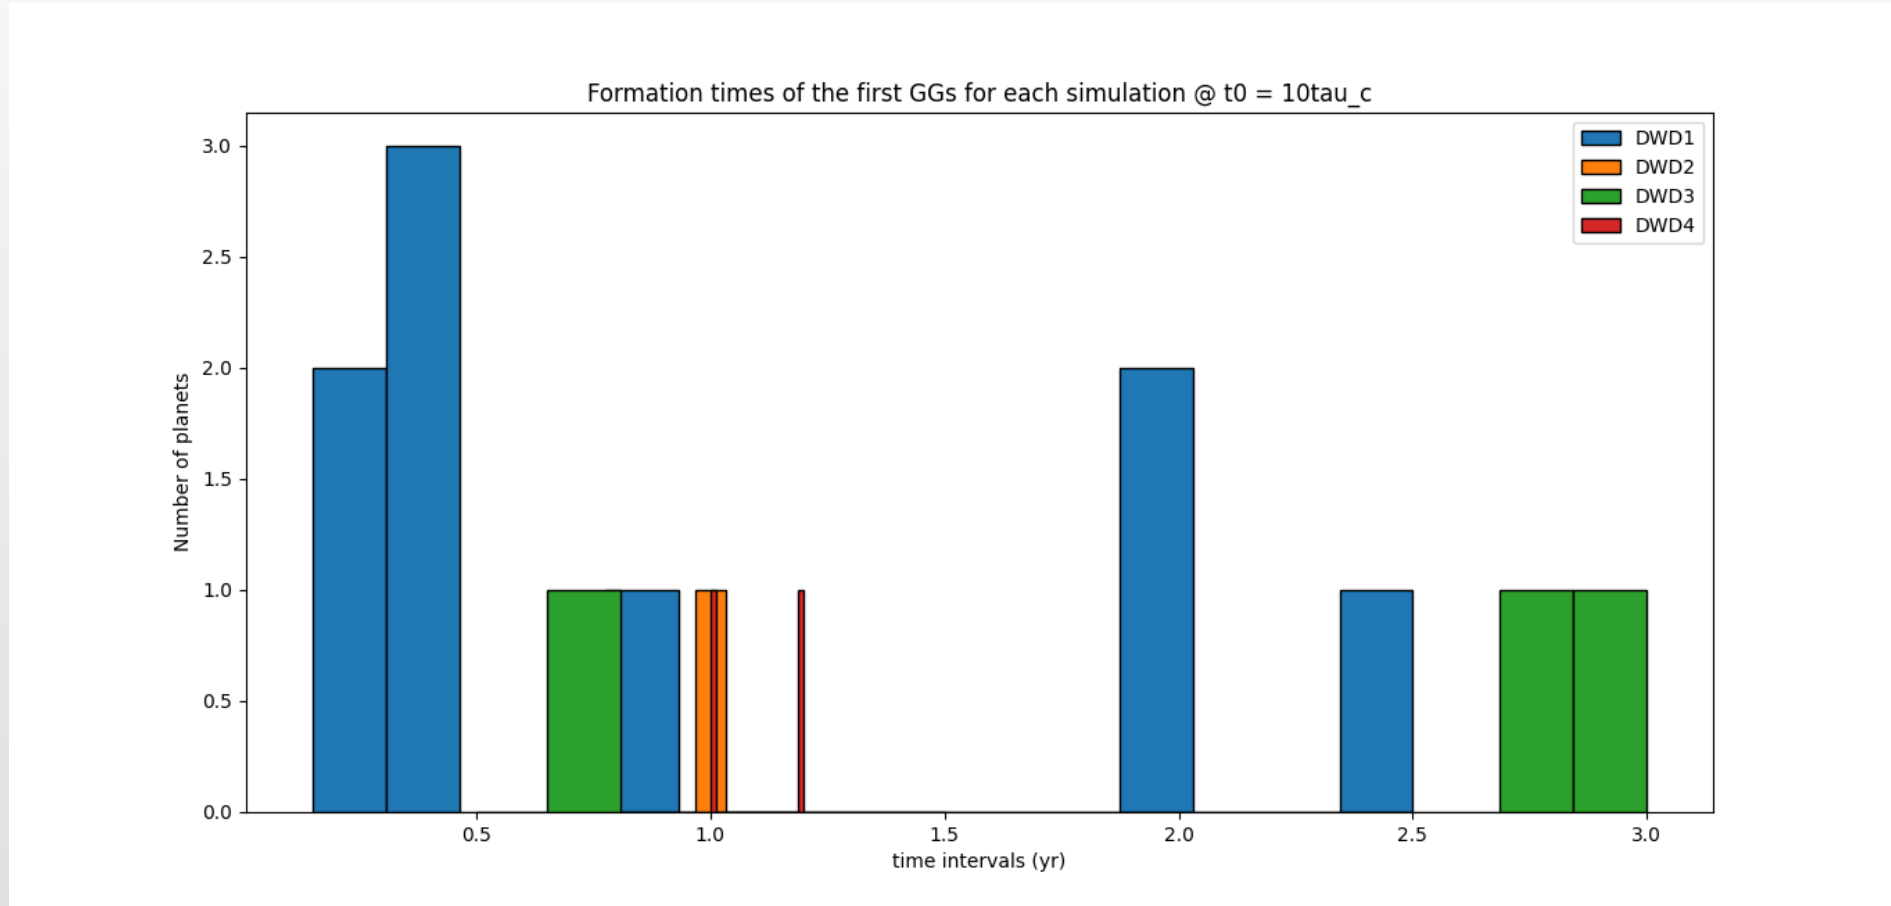

Planetary formation should be common in circumbinary discs around DWDs

- High accretion rate and dust-to-gas ratio defines the best environment for planet formation, especially for GGs formation
- GGs can form only if the disc includes first-generation seeds with masses equal or larger than the Moon mass
- The higher the photoevaporation rate, the smaller the number and masses of the GGs, and the farther their final locations
- SNs and Ns can either be of first-generation or second-generation nature, and their evolution ends within 1 AU
- DWDs can host circumbinary planets detectable by LISA during the nominal time of the mission
 - Locations within 5 au
 - Masses larger than 1 M_J
