Abstract

The source X 1822-371 is an eclipsing compact binary system with a period close to 5.57 h and an orbital period derivative \( \dot{P}_{\text{orb}} \) of 1.51(7)\( \times \)10\(^{-10} \) s s\(^{-1} \). The very high value of \( \dot{P}_{\text{orb}} \) is compatible with a super-Eddington mass transfer rate from the companion star, as suggested by X-ray and optical data. The XMM-Newton observation taken in 2017 allowed us to update the orbital ephemeris and verify whether the orbital period derivative has been stable over the past 40 yr.

Analysis method

We added two new values obtained from the Rossi-XTE (RXTE) and XMM-Newton observations performed in 2011 and 2017, respectively, to the X-ray eclipse arrival times from 1977 to 2008. We estimated the number of orbital cycles and the delays of our eclipse arrival times spanning 40 yr, using as reference time the eclipse arrival time obtained from the RXTE observation taken in 1996, for a total of 32 points.

Results and Conclusions

We fitted the delays as function of cycles adopting a quadratic model, obtaining \( P_{\text{orb}} = 5.57062957(20) \) h and a \( \dot{P}_{\text{orb}} \) value of 1.475(54)\( \times \)10\(^{-10} \) s s\(^{-1} \). The addition of a cubic term to the model does not significantly improve the fit quality.

We also verified whether a gravitational quadrupole coupling produced by tidal dissipation could be detectable in our data. To this aim, we substituted the quadratic term with a sinusoidal one in our model and then we added a quadratic term also (LQS model). However, the improvement of the fit was at a confidence of about 2σ with respect to the quadratic model.

Finally, we searched for the NS spin frequency in the XMM-Newton/Epn data, determining a spin-period value of \( P_{\text{spin}} = 0.5915669(4) \) s and its first derivative \( \dot{P}_{\text{spin}} = -2.595(11) \times 10^{-12} \) s s\(^{-1} \).

Our results confirm the scenario of a super-Eddington mass transfer rate; we also exclude a gravitational coupling between the orbit and the change in the oblateness of the companion star triggered by the nuclear luminosity of the companion star.
