Solar radio emission as a tool for identifying geoeffective solar phenomena

Wednesday, 8 September 2021 11:13 (13 minutes)

Powerful solar phenomena, such as flares, coronal mass ejections, affect the space environment, the dynamics of near-Earth space. As a rule, sudden disturbances in the near-earth space environment can cause disruptions in the operation of various communication systems, of ground-based electrical energy systems. In this regard, it is relevant to develop recommendations for identifying geoeffective solar phenomena that cause unfavorable magnetic ionospheric disturbances. The use of solar radio emission for solving the problems posed seems to be effective due to the fact that practically all processes occurring on the surface of the Sun and its atmosphere are reflected in radio emission. The report presents the main results of studies on the development of methods for determining the degree of geoeffectiveness of powerful and proton solar flares, coronal mass ejections from solar radio emission data.

The work was carried out under the project No. 0729-2020-0057 within the framework of the basic part of the State assignment of the Ministry of Science and Higher Education of the Russian Federation.
