

SPHERE

Detection and characterization of very young planets

Raffaele Gratton
INAF - OAPD

SPHERE

☼ ALMA data revealed a number of structures in disk around even very young stars

Andrews+ 2018

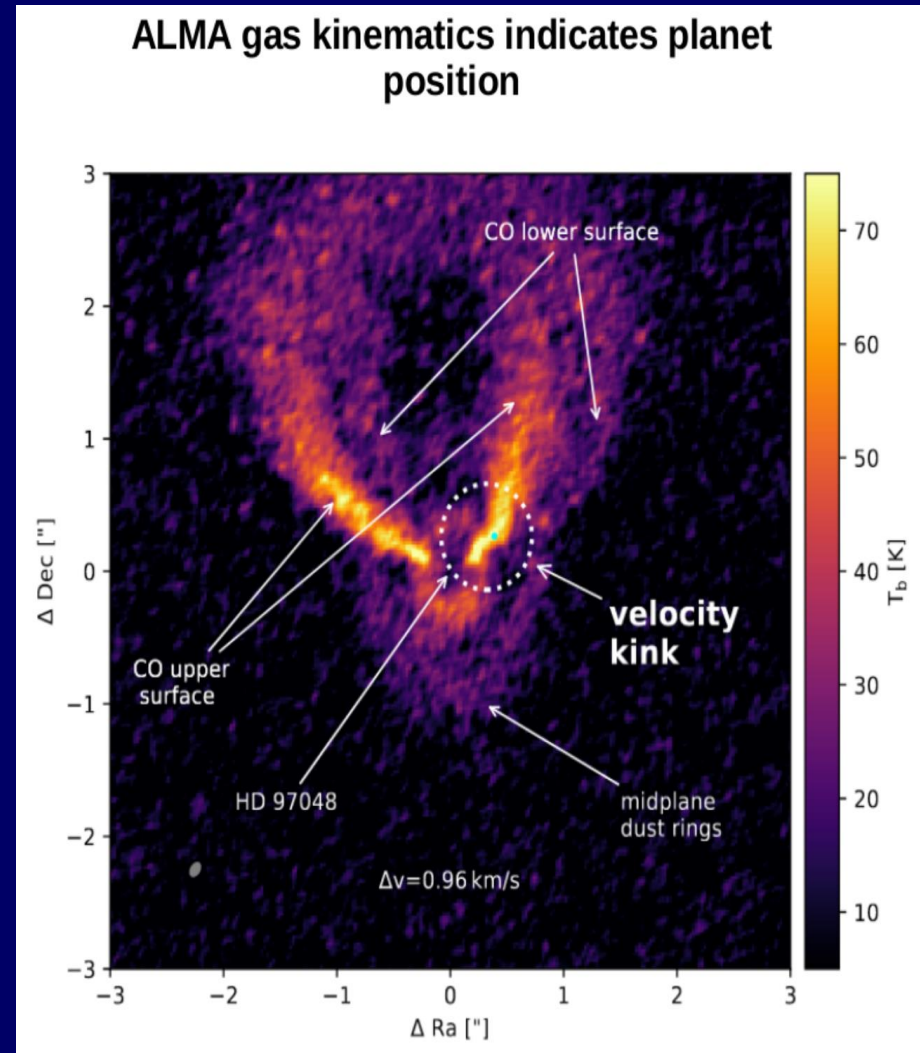

ALMA DSHARP sample – dust continuum

SPHERE

- ☀ This suggests that planets form very early within disks
- ☀ But where are these planets?
- ☀ Only indirect (and possibly ambiguous) evidence from ALMA data

Pinte et al. 2019

SPHERE

- ☼ We need direct observations of extremely young, still forming planets
- ☼ This requires high contrast imaging in the NIR
- ☼ But how a very young planets should look like?

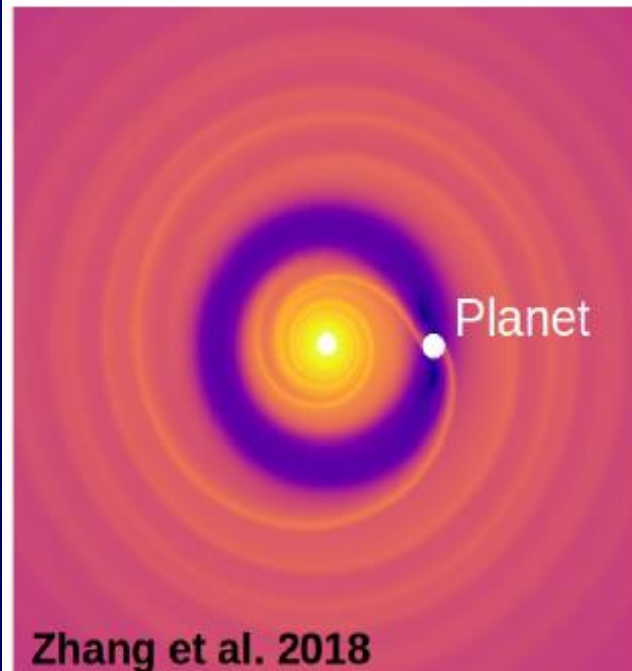

SPHERE

What we expect?

Gas

ALMA Band 6

VLT/SPHERE H-band

SPHERE

HD169142

- ☀ HD169142 is a $\sim 1.7 M_{\odot}$ star:
 - ☀ Age 5-11 Myr (Blondel+ 06; Manoj+ 07)
 - ☀ Almost face-on gas-rich disk ($i=13^{\circ}$: Raman+07); NaCo+ALMA
 - ☀ Parallax 8.77 mas (GAIA DR2)
 - ☀ Two candidate planets proposed (Biller+, Reggiani+)
- ☀ Previous studies in SPHERE GTO:
 - ☀ Ligi+: Rejection of planets, two blobs moving on Keplerian orbits
 - ☀ Pohl+: Disks clearly detected in pol. light; blobs are likely made of dust bc detected also by simulating ADI on pol images

SPHERE

Disk images

SPHERE H-band PDI (Pohl+ 2017)

Qphi image

SPHERE H-band PDI (Pohl+ 2017)

Differential imaging enhancing features

SPHERE

Blob D might be around a planet

Fig. 3. Same as the lower panel of Fig 2, but with the two disk rings shadowed (ring edges are according to Fedele et al. 2017). Blobs B, C and D are labeled

Fig. 4. Zoom of a two colour image of the region around blob D. This image was constructed using the K2 observation of JD=2458288.19 (red) and the weighted sum of all the IFS images (collapsed against wavelength) and rotated for a Keplerian motion assuming that the star has a mass of $1.7 M_{\odot}$ (blue). This last image is for the same epoch of the K2 observation. For clarity, the region within 0.28 arcsec from the star (that is within the outer edge of Ring 1) was masked in the K2 band image. The green circle is centered on the position of the blob measured on the K2 image. Note the different aspect and small offset between the position of the blob in the K2 image with respect to that at shorter wavelength

SPHERE

Blob rotation

All blobs rotate following keplerian motion

SPHERE

Blobs spectra

Fig. 6. Contrast of blobs as a function of wavelength. Blob B: Asterisks and dotted line; Blob C: triangles and solid line; Blob D: diamonds and dashed line

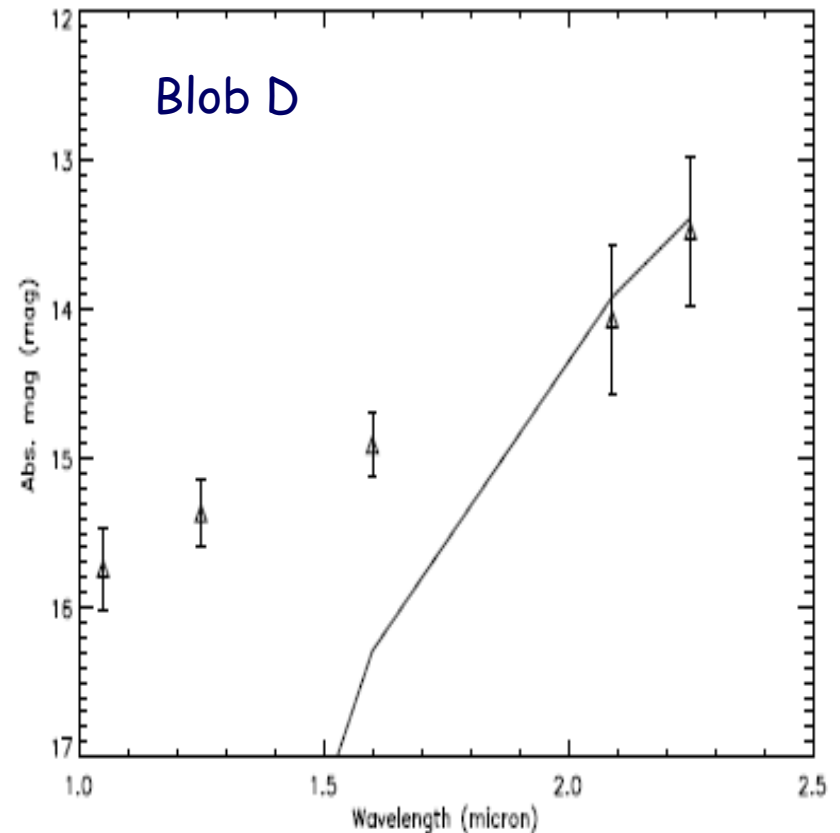

Fig. 7. Absolute magnitude of blob D in various bands (diamonds). The solid line is the prediction for a $3 M_J$, 5 Myrs old planet using dusty isochrones by Allard et al. (2001)

SPHERE

Three spiral arms

Polar coordinates

SPHERE

Planet b (?) mass determinations

- ☀ Photometry (depends on models and age): $\sim 3 M_J$
- ☀ Hill radius: $16.5 \pm 5 \text{ mas}$ @ $326 \text{ mas} \rightarrow 0.25\text{--}1.6 M_J$
- ☀ Spiral arm separation (Fung & Dong 15): $127.2 \text{ degree} \rightarrow 5.1 \pm 1.1 M_J$
- ☀ Pitch angle (Zhu+ 15): 17.5 degree @ $183 \text{ mas} = 0.55 r_p \rightarrow q=0.006 \rightarrow 6 M_J$
- ☀ Disk gap (depends on disk thickness and viscosity):
 - ☀ Kanagawa+ 16: $0.75 M_J$
 - ☀ Dong & Fung 17: $0.56 M_J$

SPHERE

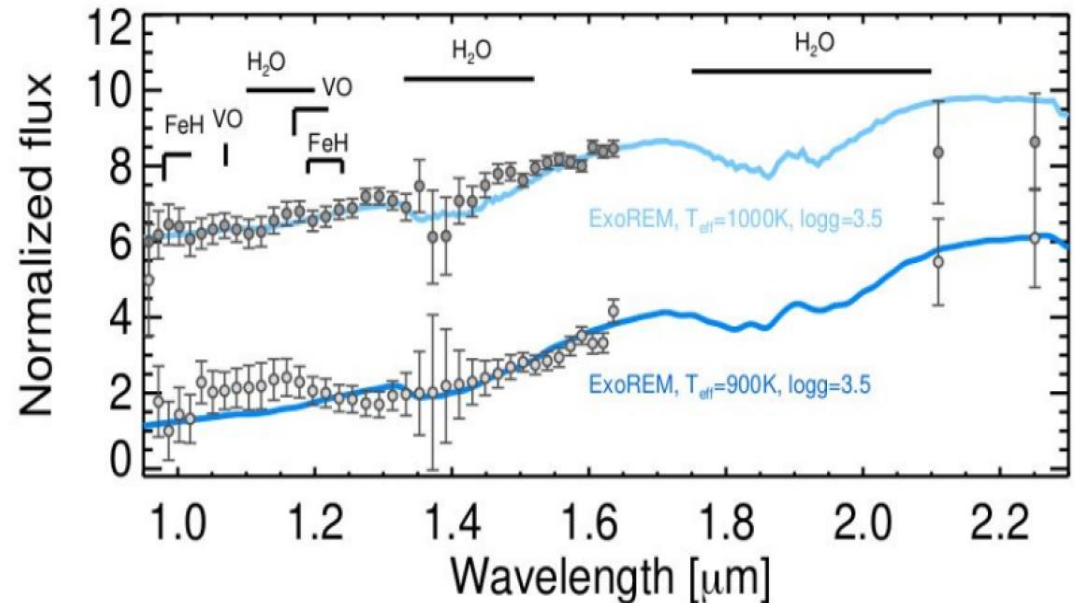

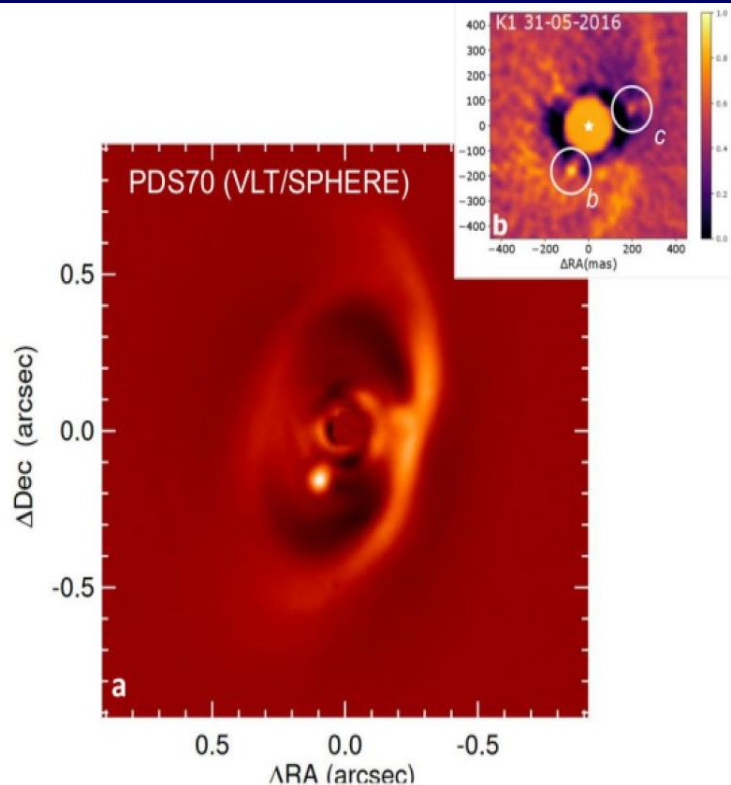

What are blobs B & C?

- ☼ Blobs are near the 1:2 resonance of the proposed planet (around blob D)
- ☼ They may be vortices (discussed in Ligi+)
- ☼ Alternatively, they may be clouds of debris generated by the collision of asteroids

SPHERE

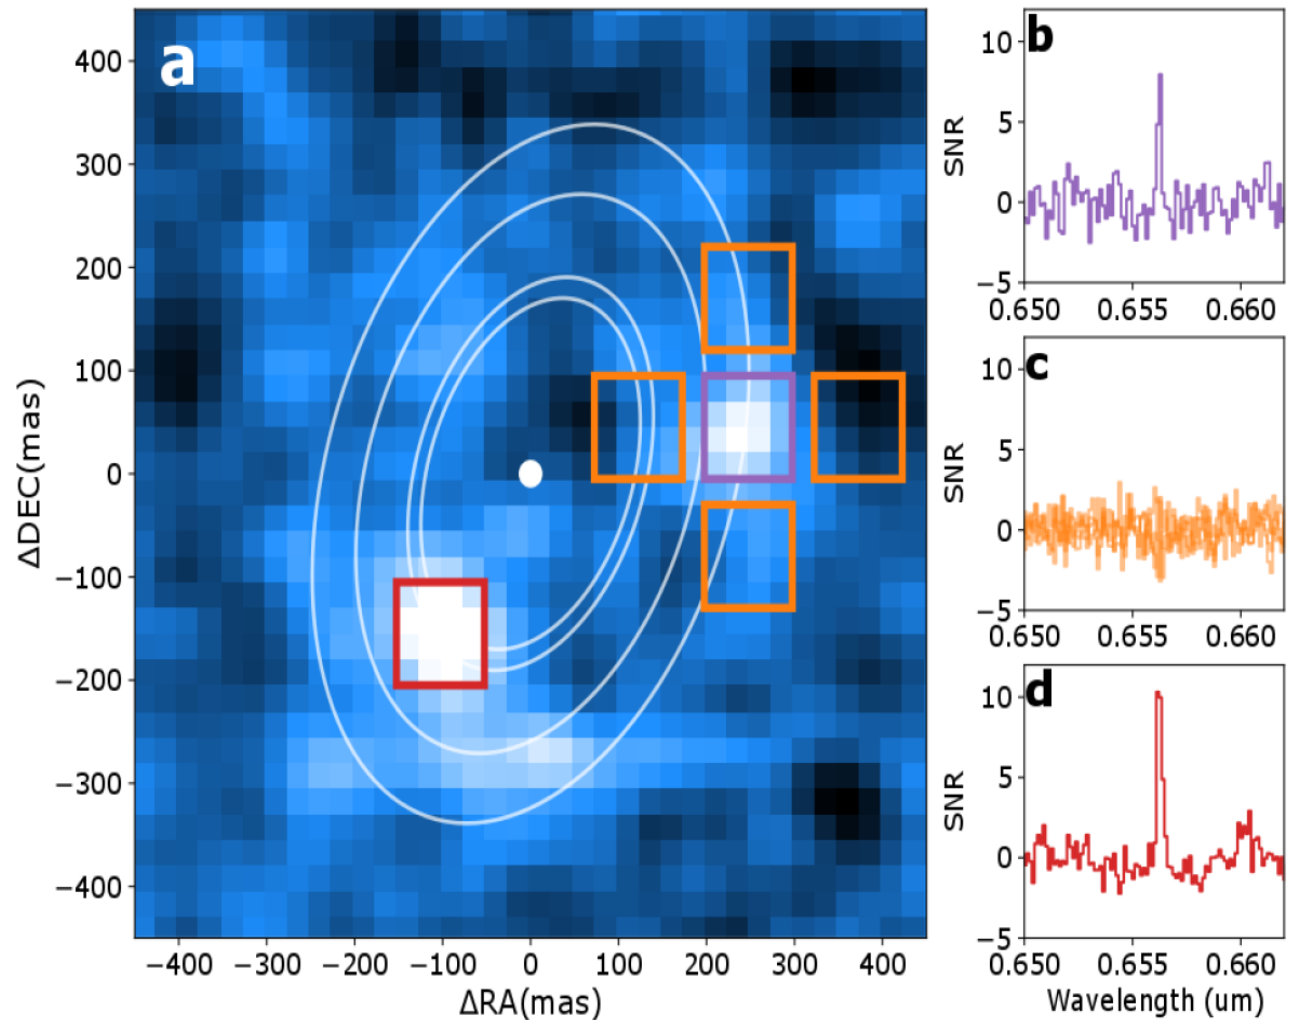

PDS-70

A system with a planet embedded in a gas-rich protoplanetary disk around a 6 Myr old solar type star ($\sim 0.7 M_{\odot}$)

SPHERE

Haffert et al
2019:
Two accreting
planets
detected from
H α emission
with MUSE

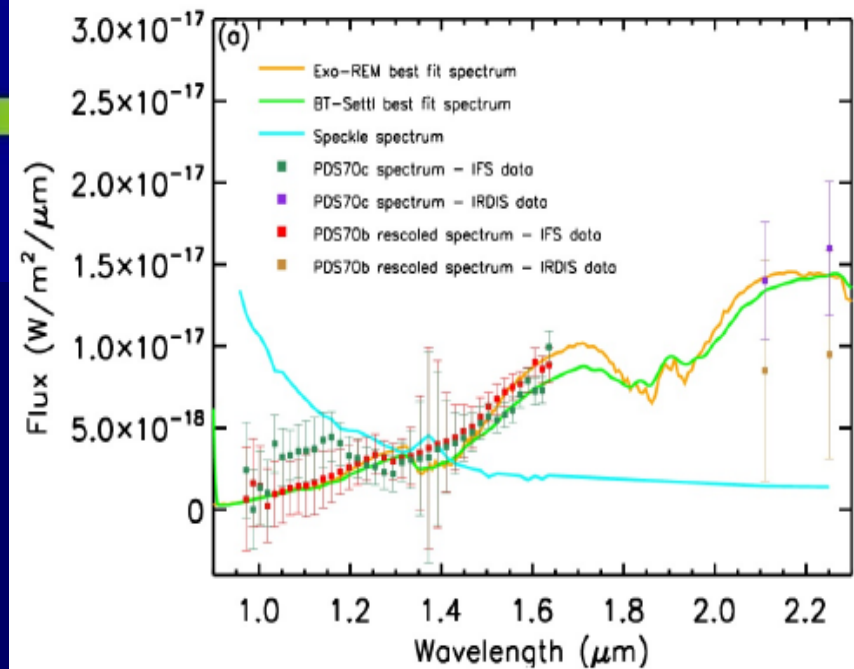

SPHERE

Cc around PDS-70

Mesa+ 2019: Two, perhaps three planets

SPHERE

Conclusions

- Detection of still forming planet is crucial to understand the mechanisms of planet formation
- Very young planets are very red and dusty, are likely still accreting, and may be surrounded by a circumplanetary disk that reflects star light
- Confusion with disk features is a major issue, mainly so if the system is not seen face-on
- We need:
 - High contrast
 - Very high resolution
 - Wide spectral coverage, possibly using IFS
 - Combine with info from polarimetry and ALMA
